In other words, the worse condition the plant is in, previous to the adoption of the system, so in like proportion will the results take to show themselves. In the ordinary shop at least a year of hard work, and co-operation, is necessary to bring about tangible results.

The writer strongly emphasizes the point, namely, that no system, no matter how good, can work miracles. If previous to the installation of such system, the trend of work was carelessly attended to, it is only to be expected that some time must elapse before conditions change for the better. Common-sense will tell us that, and yet many a system has been thrown out because in a month's trial no appreciable result had come to the surface.

What then constitutes a correct cost system?

The writer would say, one which is proven cost system, so arranged tha we actually know and see direct ben fits, not theoretical ones.

It often happens that some scheme tried and proven successful in anothe plant, can by intelligent understandin of its basic principle, be so arranged an adapted to be successful in anothe plant, but in every case it should b recognized that we cannot take som system holus-bolus out of one plant, an dump it into another altogether differ ent line, without some modifications.

Before going into the subject o graphs, let us consider one more point namely, the correct type of man t handle such a system.

The writer personally believes th correct party for such a position is a efficiency engineer—but wait (for in m ears I hear numbers saying, "What, a efficiency engineer? Not on your life I've been stung once—never again." Unfortunately, many have been hood winked by so-called efficiency engineers but were they? In other words, wha constitutes the make-up of a **real effi ciency engineer?**

Webster defines efficiency as follows "Of being efficient, or producing an ef fect or effects, power or action. The

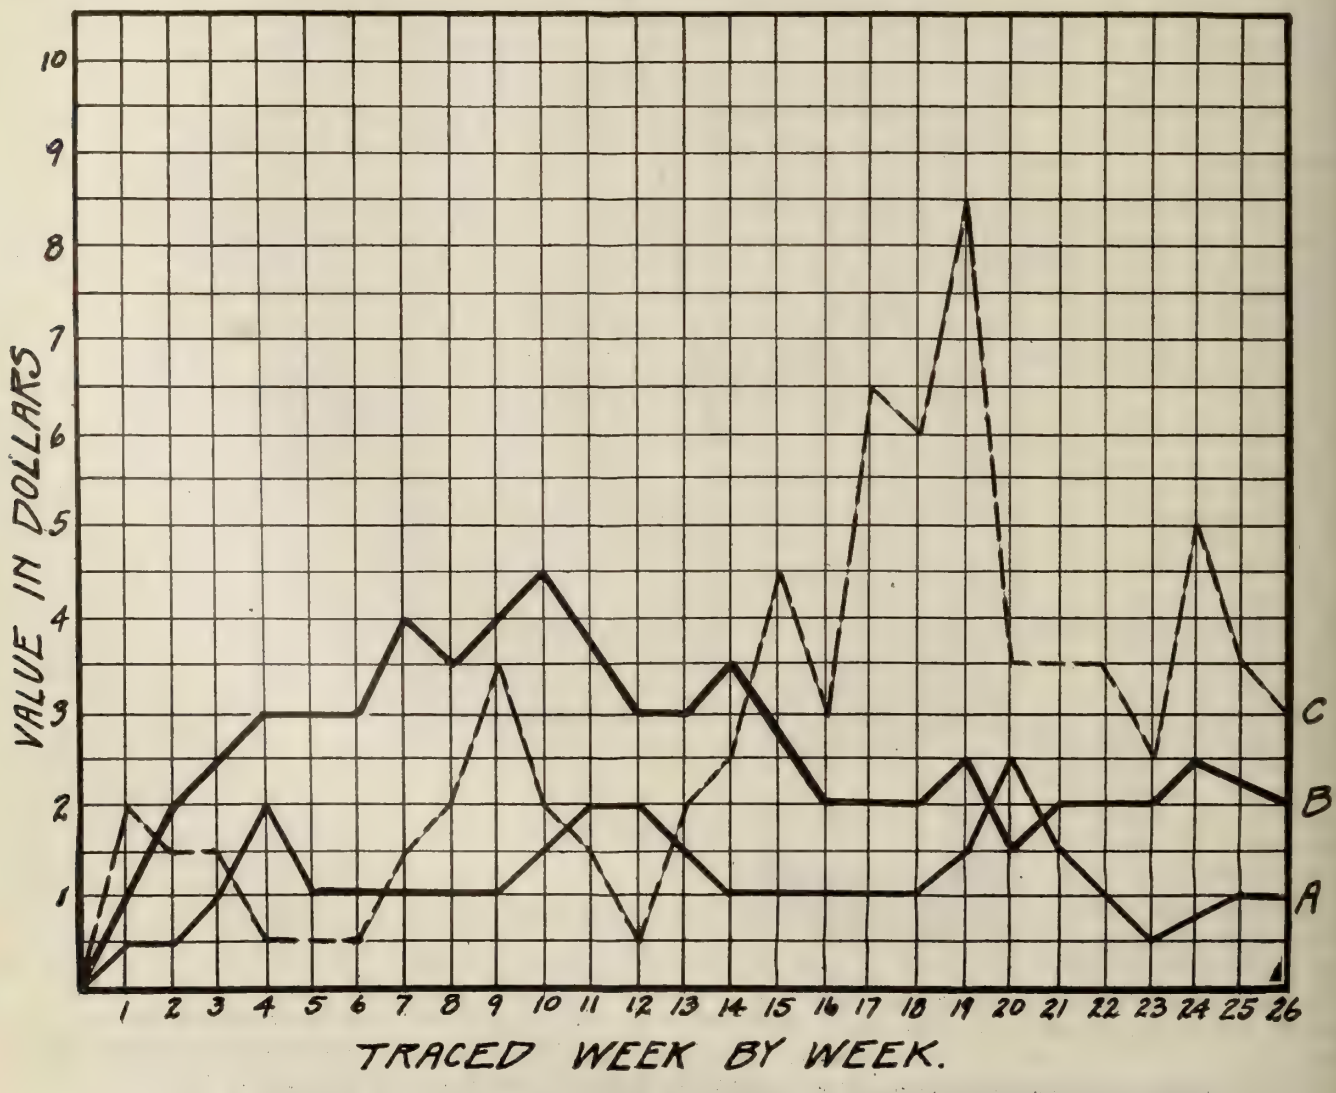

FIG. 2.—SHOWING UP CLEARLY THE WASTE IN MATERIAL BY THREE DIFFERENT DEPARTMENTS.

ergy or work that is got out of a machine," etc. We could go on indefinitely—but the main theme is results to a maximum point.

To obtain maximum results from all angles, the engineer must first be a practical man, who understands that these angles exist. For instance, we could not expect a man who has sat over a desk in a wholesale grocery office, to leave his position, step into a large machine plant, and bring this shop up to a maximum producing point, providing it was in bad shape of course.

This parallel may seem ridiculous, yet there are some fellows posing as efficiency engineers who have tried to rearrange business concerns, whose policy they have not even been familiar with.

The writer personally knew of one chap who was a machine efficiency expert (?). This fellow talked good, had a splendid appearance, and sure held the bluff down fine. This we give him credit for.

To see him stand at a machine chat-

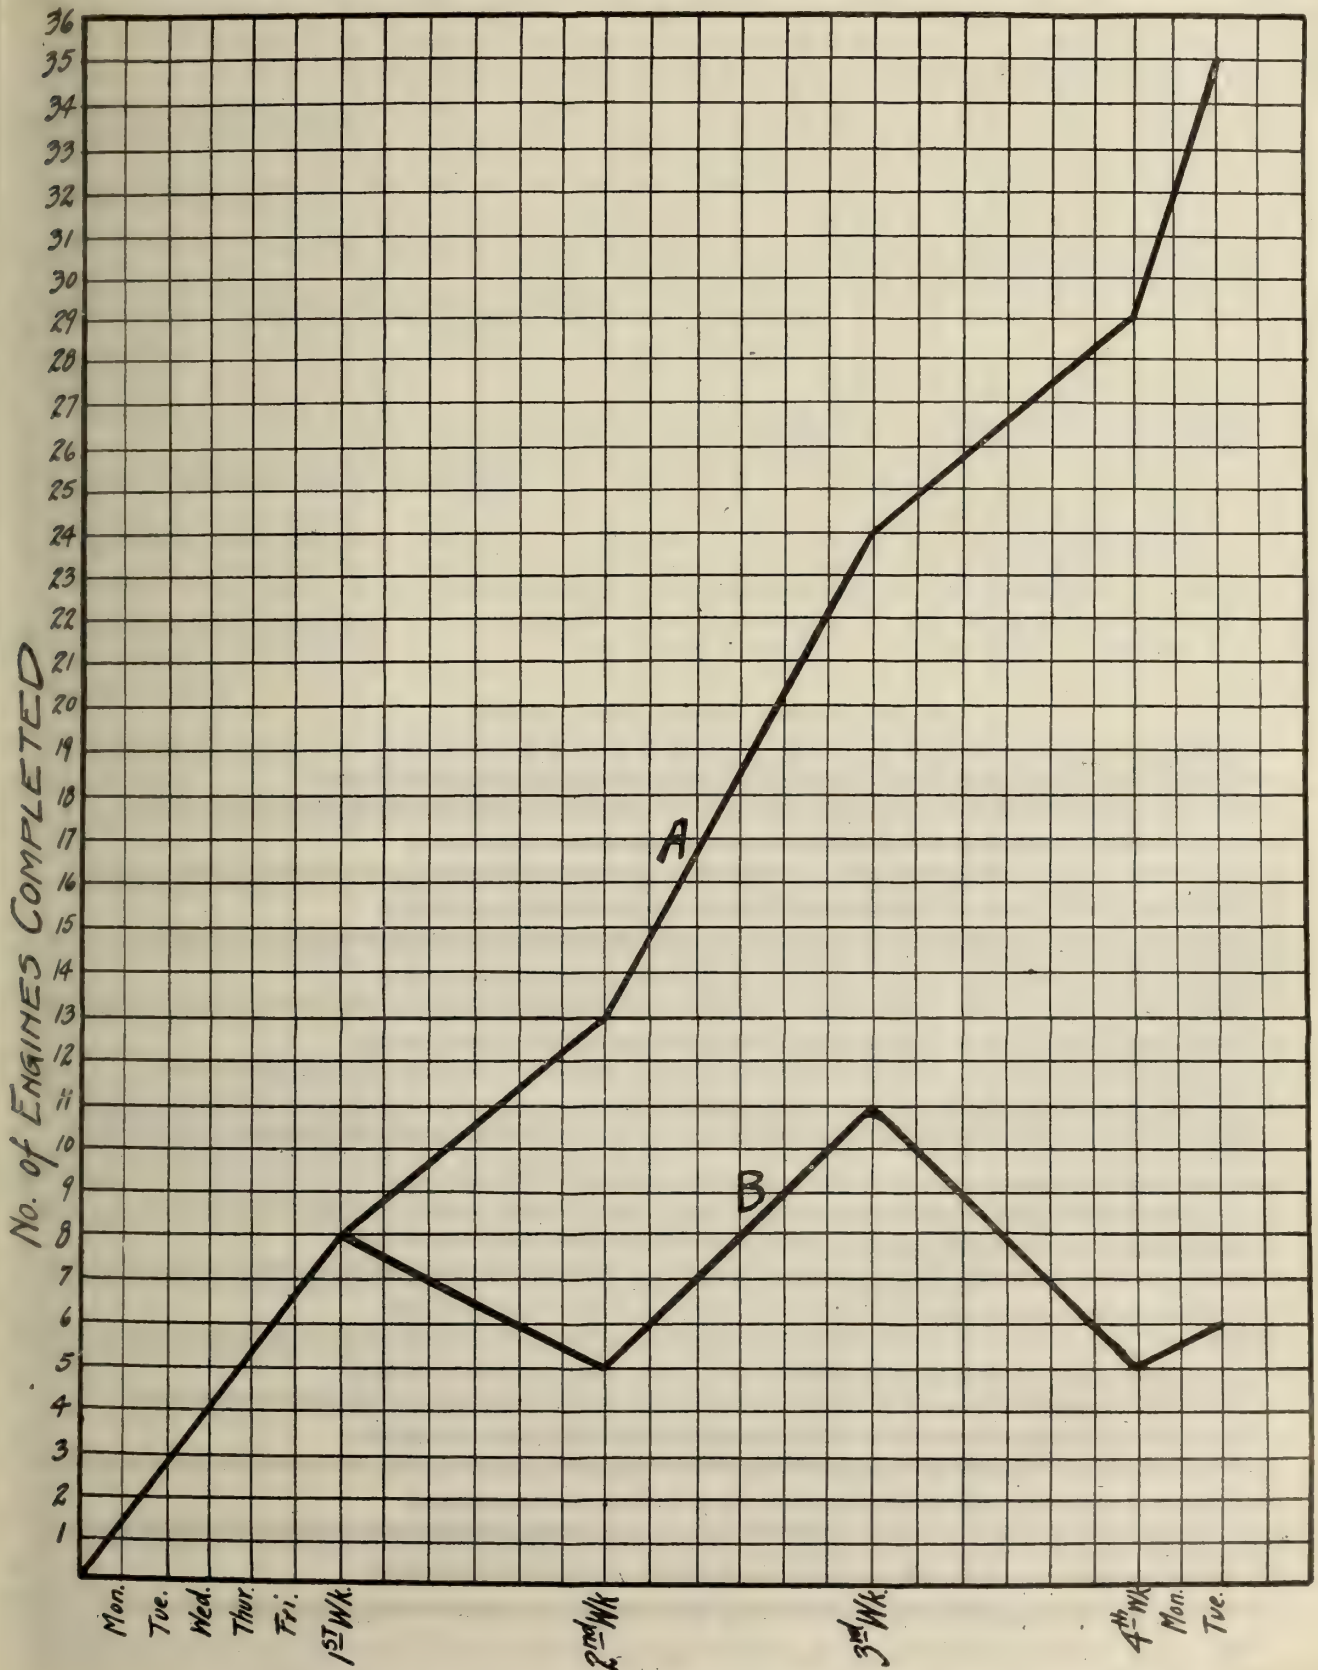

FIG. 3.—ILLUSTRATING THE FLUCTUATION WEEK BY WEEK, AND TOTAL PRODUCTION PER MONTH.

ting with a man was a treat. The operator felt good, so did the engineer, for he had his stop watch on the go at the proper moment, and later figured out the time of operation. It took the workmen some time to figure out why their time was being cut, until they suddenly caught Mr. Efficiency red-handed. Of course what happened is obvious and natural. They beat him up, which he deserved.

Granted that first this firm was wrong for employing such a method, and man, and second, that such a party as spoken of is a bad example, yet the point is this, that previous to his position with this firm he had run an Ice Cream Store, and read up books on the subject of efficiency in the meantime.

He went back to his business where he belonged, and his wife who had kept store for the time being scrubbed her floors once more.

But all this is deviating from the main point, namely, what is an efficiency engineer? In the writer's opinion it is a person thoroughly acquainted with all the ins and outs of the business which he proposes bringing up to a high standard of efficiency. A good practical man. If it is in the engineering line, he should be a thorough, highly educated mechanic, both in theory and practical knowledge. His scope should include the pattern shop, foundry, machine shop, routing in all its phases, etc., etc. It is the fact that he possesses these qualities, which distinguishes him from the ordinary mechanical superintendent, who might be an ideal mechanical man, but mighty short on theory, and lacking in imaginative qualities.

Taking it for granted that readers are in accordance with the writer, we will go on with the subject of graphical solutions of manufacturing cost. No attempt will be made to show a complete cost system. Such an article would cover more space than herewith laid out, but we will cover important ground with the following five graphs, or charts as they might be called. For illustrative purposes the writer has drawn on his personal experiences in the gas engine, and machine tool trade, and quotes figures which he has actually proved to be correct, practical figures, and not merely theoretical. This is especially true of the chart showing the difference in costs, with and without jigs, for the work.

In a certain manufacturing concern, producing a well-known type of machine tool, the cost was proving exceedingly high. No actual trace was being kept of these costs, but the end of the year showed plainly something was radically wrong, so the result was that charts were prepared of the various operations throughout this tool's manufacture, to see where the trouble lay.

Planing, shaping, drilling, milling, assembling, etc., etc., were all covered, and figure 1 illustrates how the planing operation showed up. These machines were (as is usually the case) turned out in batches under various numbers. The graph was made to accommodate this fact. Referring to the illustration we see that on the vertical scale we have the cost in dollars, while the horizontal scale is marked A.B.C.D.E.F. Each of these letters represent an order number, and of course a batch of machines.

From a low record cost of $60.00, these costs soared to $139.00. Impossible you say—yet such was actually the case. Of course after seeing such results, trouble ensued, and no wonder, for plainly something was very far wrong. It later developed that the planer hands were not evenly matched as regards ability. Readers might reasonably enquire—then why were they allowed to stay? This also cropped up on further enquiry, namely that they were friends of the foreman's. All this sounds fishy, but it actually happened. For obvious reasons the writer cannot give this definite information.

Of course this state of affairs was remedied at once, with the result that the operation cost became normal once more and stayed there. Without some cost system, this item would have been exceedingly hard to trace, in fact might never have been traced to the exact source where most of the trouble lay.

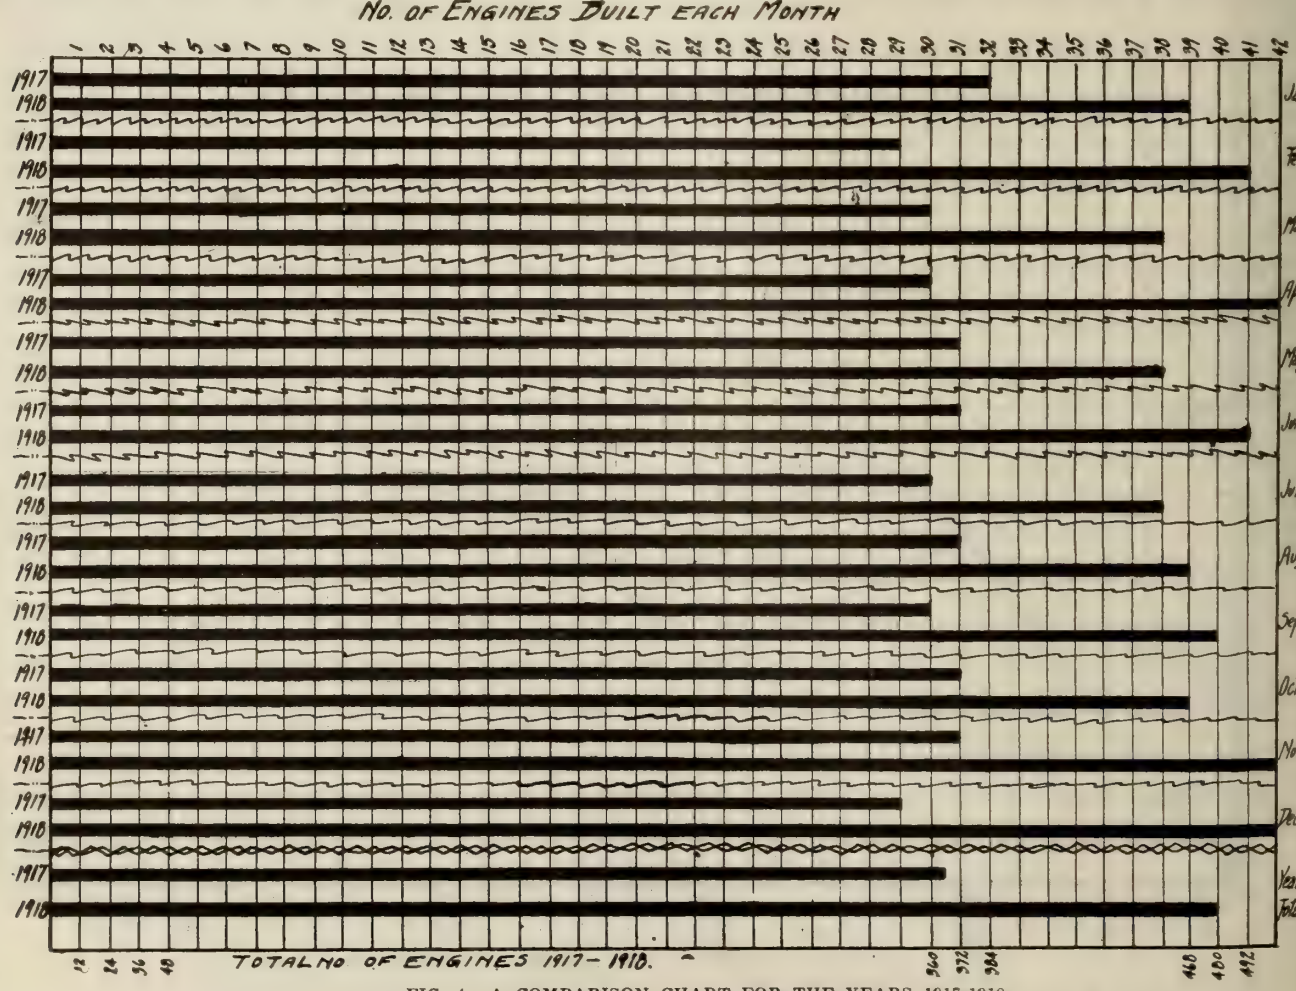

FIG. 4.—A COMPARISON CHART FOR THE YEARS 1917-1918.

The other operation charts also showed a variation in costs, but not so marked as the particular chart illustrated. Every chart on each operation was studied carefully, with the final result that this machine tool spoken of was manufactured at much less cost than formerly. Each department was placed under careful check, and production soared accordingly.

Another source of annoyance to this firm was the great amount of scrap or spoiled work. This item did not begin to show itself until the cost system got into operation. Fig. 2 shows the results in three departments.

As can be noticed the horizontal scale illustrates a half year's work or 26 weeks, while the vertical scale represents the value in dollars. The line A represents the drilling department, the line B the shaping and planing depts., and the line C the lathe department. The chart illustrates clearly that the lathe department was the chief offender as regards spoiled work, one particular week reaching a maximum of $8.50. Investigation proved that carelessness on the part of one particular workman was the whole trouble. Therefore the department itself was not to blame, but only an individual, which proves it never pays to come too hastily to conclusions, but rather it pays to investigate with an honest attempt at discovery, rather than an idea of calling some particular department over the coals. The other departments were likewise gone into, with the result that less spoiled material was turned out by this firm.

We will now go into another business altogether, namely, a firm engaged in the manufacture of gasoline engines. Things were not looking any too bright for this concern, as production seemed very erratic, and costs exceedingly high. A cost system was started and the first chart made was that of the production of engines week by week. Fig 3 illustrates this graph clearly. As can be noticed the vertical line represents the

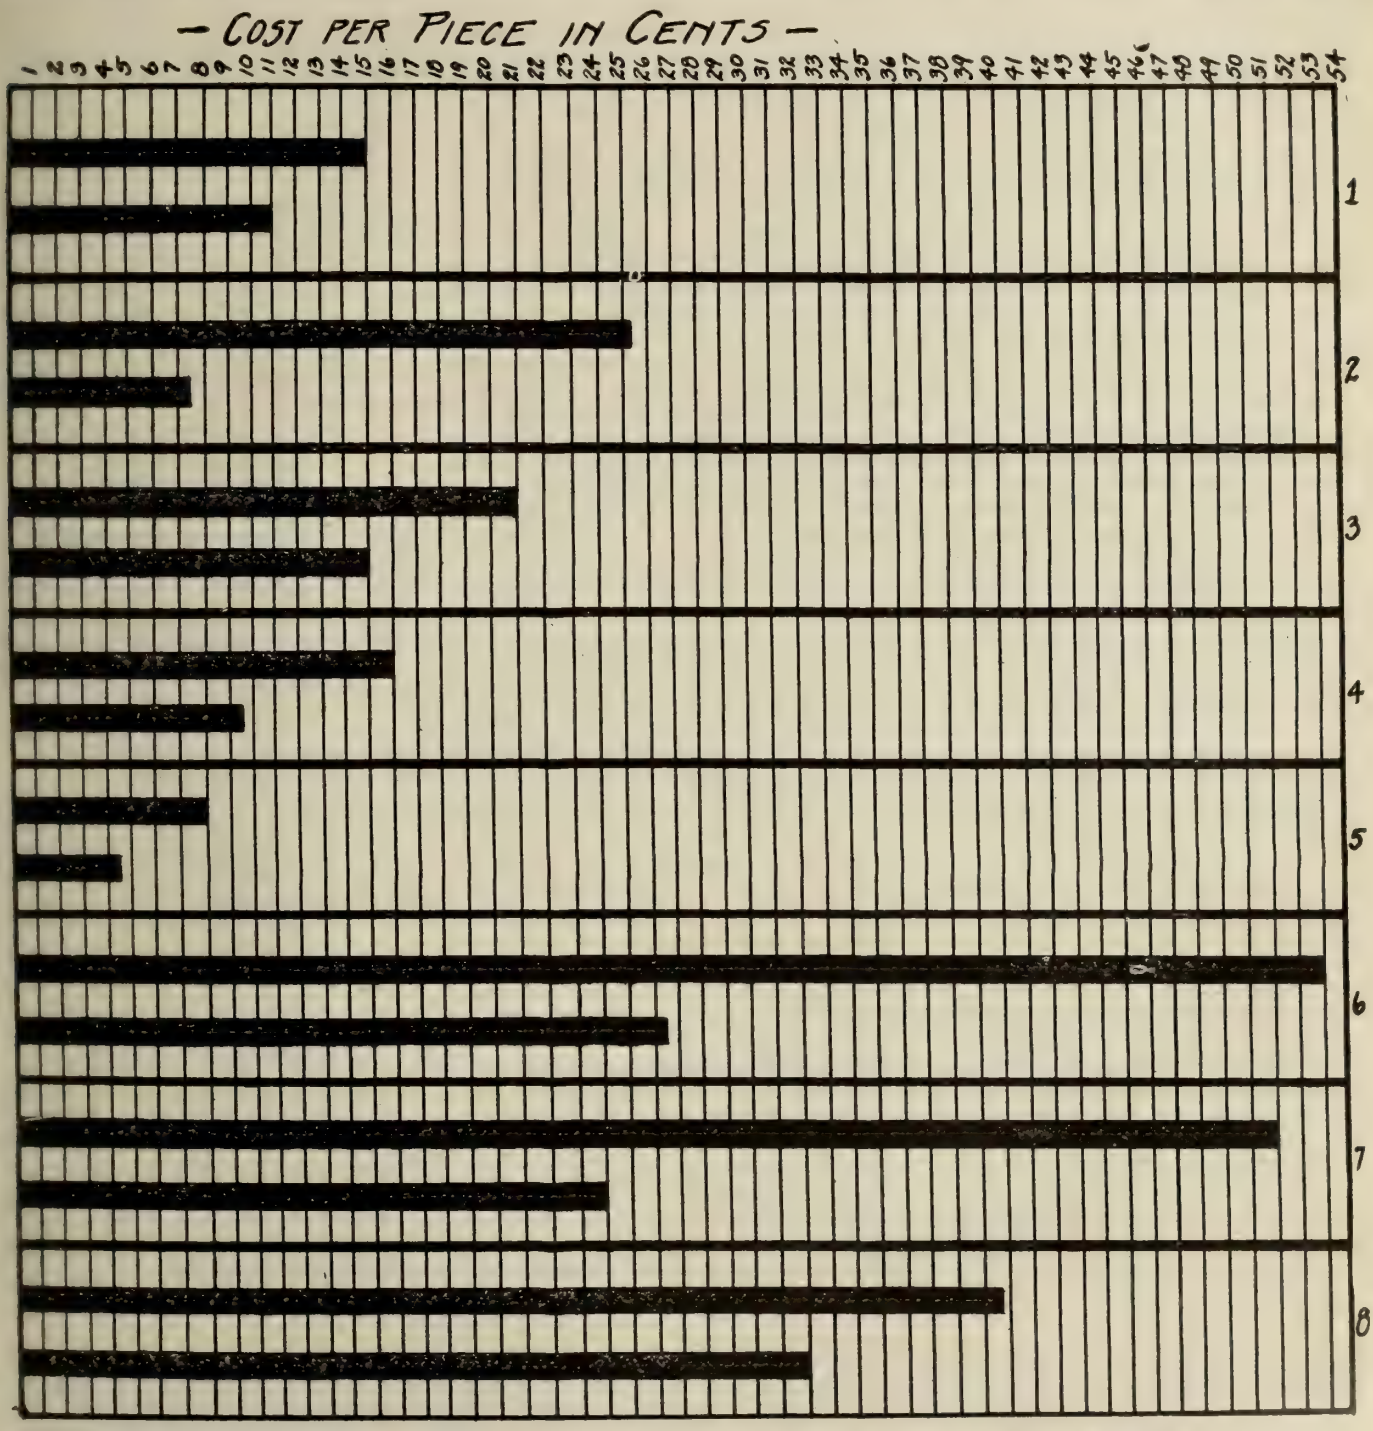

FIG. 5.—ILLUSTRATING THE POINT THAT THE INSTALLATION OF PROPER JIGS IS A PAYING PROPOSITION.

number of engines completed, while the horizontal scale shows the weeks in the month. One of these charts was prepared for each month. In the particular month shown on chart there were two working days over the four weeks.

The line A designates the gradual step in production as follows: eight engines the first week, five the second week, making a total of thirteen and so on, up to a total production for the month of 35 engines.

The lower line B represents the fluctation of production, week by week. To illustrate that it is sometimes a very little matter which hinders production, let us comment still a little further on this chart.

From 5 engines to 11 engines, between the second and third weeks, seems quite a difference, yet this was easily explained after investigation. It was through no fault of the assemblers that this difference occurred, but rather that the work from the various departments was not coming in as it should be. The result was that each assembler naturally slackened up during the week that insufficient parts were coming through.

But look what happened when the parts came through faster. Assembling soared to eleven engines, proving that with a proper study of routing operations throughout the shop, production could increase all around. Later on this theory proved a fact, and before long 18 engines were being turned out each week.

At the completion of the year 1918 a chart was made to show the differences between the years 1917 and 1918 production, with the result shown at Fig. 4.

Instead of a total of 365 engines per year, 480 engines were completed in 1918, making an increase of 115 engines, which was not so bad for the first year's improvement.

Of course, various changes throughout the plant were helpful in bringing these results about, one of the most important of which was the installation of a good practical jig and fixture plan. Wherever thought advisable a jig was made for a piece, where, perhaps, before no such fixture existed, or if it did, it was some poorly constructed affair that hindered rather than helped.

After every jig was designed and put into actual operation, close tab was kept on the new operation cost. This in turn was compared with the former cost. From these two costs a chart was made to show the difference. The result is illustrated at Fig. 5.

Here we see that the horizontal chart designates the cost per piece in cents, while the vertical chart represents by 1, 2, 3, 4, etc., a separate jig for each section. Section 1 represents a drilling jig installed on the connecting rod. Where before this piece cost 15 cents, it was made for 11 cents after the jig was used.

Section 2 represents a milling jig on the same piece, and shows what an enormous difference can be made by a really efficient jig. From a cost of 25½ cents, this piece came down to 7½ cents. These figures were carefully checked and are absolutely correct.

This can be carried right down the line, but we will only take one more example, namely, section 6. This operation was the milling of a certain portion on the cylinder. From 53 cents, the cost was reduced to 26¼ cents, with only an expenditure of $12.00 for a new fixture. In other words, the fixture was more than paid for in the first day's run.

The writer could go on with such examples indefinitely, but he has shown what he believes positive proof, that a cost system, if intelligently handled, is an absolute necessity and a wonderful money saver. In no case shown has he quoted any elaborate schemes, but rather a common-sense method of going after the trouble. These charts will no doubt suggest others equally applicable, perhaps not to the same lines, but to the machine trade generally.

Disraeli had it right when he remarked that "Economy does not consist in the reckless reduction of estimates. On the contrary, such a course almost necessarily tends to increased expenditures. There can be no economy where there is no efficiency."

With these concluding remarks the author will close his article, merely suggesting that when looking around for a cost system, look around also for the correct man to handle it. The practical system, combined with the practical efficiency engineer, cannot help but prove a winner. One without the other is useless, but combined they make a valuable asset to any business.

SOME SPEED

Miss Margaret B. Owen, who now holds the world's championship for speed on the typewriter, certainly tickled the old keyboard, for she pounded out 137 words a minute for one hour. This means she had to hit the keys 12 times every second, which is faster than the ordinary person can dictate. It took seven years of determined struggle before she attained this record.

HATS OFF TO HORSEMINT

Are you aware that when you use your tooth paste you are indebted to a weed called horsemint? This weed grows wild in great abundance in Wisconsin, and is used in tooth wash, and tooth paste almost exclusively. The next time you feel that clean, refreshed feeling of the mouth, praise the wild weed, horsemint.

STARTING EARLY

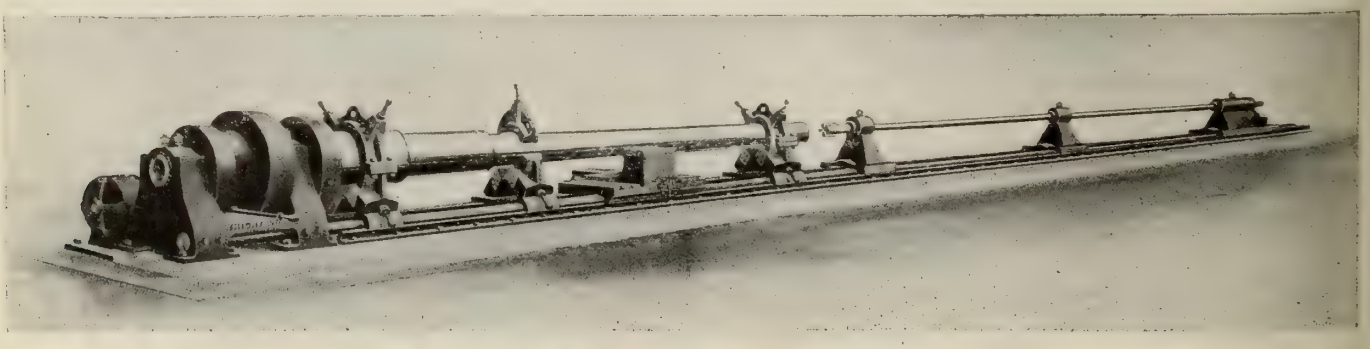
A Cincinnati high school lad, who is rather inclined to model building, has succeeded in building the following models: Submarine chasers, airplanes, and racing car. The car has only a wheelbase of six feet, and has a two-cylinder motor, yet is said to be able to travel at 70 miles per hour.

SOME DUEL

Out of Africa comes the thrilling story of how a lioness and a six cylinder car fought an exciting duel. The car and animal met head on, with the result that soon the lioness was no more. A dent in the car's radiator was the only damage to the car.

THE FIRST PAPER

What is believed to be the first daily paper published was called the "Daily Courant." England was its home, and it appeared in the form of a single sheet, printed on one side only. This paper appeared in the year 1702. Compare this with the paper of to-day, yet this occurred not much more than two centuries ago.—J.H.M.



NOTABLE GUN-BORING MACHINE ON CONCRETE BED.

They All Refer to the Labor Troubles Here

Industrial Leaders in Various Canadian Centres Say Strikes Are Causing Business Interests to Hold Back—Many United States Firms Are Coming to Canada Very Soon

WHEN the war ended last November business men looked with considerable uneasiness to the winter. A large part of the energies of our manufacturers had been diverted to the making of munitions, and in many cases manufacturers had given a heavy hostage to fortune by taking a chance on the war continuing for several years. It was with that expectation that the United States made their war plans.

Those who got into the game of munition making early in Canada were able to write off the heavy expenditure on plant and machinery which was, in large part, useless for peace purposes, and made a good deal of money. To those who began later, fortune was not so kind, and many actually suffered loss from the munition making business. For all there had to be a sudden reversion to peace production again, and even yet things have not begun to run smoothly in their old channels again. The expected trouble was not so severe last winter as was anticipated. The returned men were demobilized gradually, and the gratuity given them enabled them to tide over the winter. There is, as yet, no serious congestion of labor, although some people are looking with some anxiety to the coming six or eight months.

The labor disturbances throughout Canada have been a serious economic mistake. One of the most serious hindrance has been in the building trade. As Mr. Hobson, head of the Steel Company of Canada, pointed out to CANADIAN MACHINERY when interviewed at Hamilton a few days ago if labor does not get down to business soon there will be no building done this season, which will make things bad for next winter, whereas if the walls and rough work were finished now there would be inside work provided for next winter.

"Business conditions are improving steadily," said Mr. Hobson, "and a great deal depends on labor. The steel business is picking up in the United States, and that will likely be reflected here to some extent. Our largest blast furnaces have been under repair for some time and will be blown in again about the 20th of July. We got out of war work before the end came. Our war sales in November were only about 11½% of our output. We never refused to supply anything the Government wanted, but we did not seek war work.

"Everyone realized that it would take some time to get back to a peace basis, and I advised our shareholders of that as far back a 1916. When the war came there was really a much worse upset of conditions than there is now, and times were worse. Canada has a big task before her; but she has also more wealth than she ever dreamed she would have. Our employers took over two million dollars' worth of Victory Bonds. We should not have much trouble in coming back." Referring to the demands for wage increases, Mr. Hobson said: "There has been no demand made by our own men at all. It has been made by the agitators. Our doors are never closed to our workmen. Our men all went out at Swansea, but it was a sympathetic strike. They made no demand on us at all."

Getting Back to Old Shape

Mr. Pook, manager of the Canadian Westinghouse Company, said there was a very good feeling between employers and workmen in Hamilton. The manufacturers and labor people had got together. "We cannot always give them all they want, but in this plant if a man has any grievance I am always ready to talk it over with him. We have many old employees who have stayed by us, and I think they realize that they will get a square deal. At present we are working out a mutual benefit association which will provide cheap insurance.

"We are not completely over the period of readjustment in Canada since the war. It upset things considerably, as we had to have new standards; but we are getting back with satisfactory speed. After the armistice there was a slump in business, but it is coming back now. Even during the war-time rush we tried to keep up with our regular work. We made a great deal of machinery in the way of presses and work for ships, and tried to keep both ends going. The most of the shell machines were scrapped, although a few were rebuilt for rough work. In our case it was lack of business that kept us from getting back to stable conditions more quickly. We are not altogether through the readjustment period yet, but our people have been very reasonable, and we try to reciprocate. We have a 48-hour week here, working 8 6-10 hours for five days and 5 hours on Saturday. There does not seem to be much unemployment in our line. While we are not working full time, we expect that when the grain begins to move production will increase."

The Cause of Labor Unrest

Mr. John Muir, of Goold, Shapley, Muir, Brantford, has some very interesting views on the tariff and other questions, and has what would generally be called rather an unusual viewpoint for a manufacturer. Regarding labor and industrial conditions, he says there seems to be an abundance of labor but very little "labor trouble." Some months ago there was a good deal of agitation in Brantford, but it has quieted down. The manufacturers and the men have had frequent interviews and there was always a good spirit shown. "The unions are on to the Bolsheviki," said Mr. Muir, "and if they appeared here they would be chased out."

"The implement business is rather dull at present. There are bad reports from the West and we have not yet got settled down to proper export buiness conditions. One of the big causes of labor unrest has been that very high wages were made at munitions, and this demoralized conditions in other industries. We had good men here at $3.75 a day, and when we began to make munitions—for which work you could train any ordinary man in a week or so—they saw their fellow employees—green men—making six or seven dollars a day. This naturally caused dissatisfaction. The result was that we had to raise wages all around time after time. There were six munition plants in Brantford. When the munition work closed down there were a number of what might be called second-class men. When they were offered less pay than they had been making at munitions, some of them began to agitate.

"The attitude of the men with regard to agitation has been good, however. I'll tell you a story to illustrate it. Among the workmen we had was a Russian. When the war ended the men had a little dinner among themselves at which this man was present. When the toast to the King was proposed he refused to stand up, and he did the same thing when "God Save the King" was sung. The result was that the men refused to work with him any more, and he had to get out. Some months afterwards he was around distributing seditious and Bolsheviki literature, but he made no headway. I believe in giving labor credit every time, and their attitude here has been good.

"Conditions in the West are pretty bad. I came back

from there three weeks ago. The C.N.R. was tied up with the labor trouble, and our different branches could not ship. Where the drouth was bad, we had orders not to ship goods unless it rained. When I came back I naturally decided we should go slow in manufacturing, which means a reduction of hands.

"It is up to the manufacturers to make every possible effort to get foreign trade, otherwise we shall have a dull winter. That, in my mind, is the solution for the labor question in Canada to-day. We are doing our utmost in that line and have arranged with a big Montreal firm to handle our lines for the Balkan business."

Getting Export Business

Col. Harry Cockshutt, of the Cockshutt Plow Co., says the class of labor they receive is none too plentiful. Their plant is now closed down for inventory, etc., but the prospects for future business are fairly good, though the effect of the crop failure will likely be felt later on.

"As we have attended strictly to our own business and not made munitions," said Col. Cockshutt, "the transition from war to peace did not affect us very much. We kept our organization intact as far as possible during the war.

"With trade conditions uncertain and unrest among labor it is necessary for business men to go carefully in all their undertakings. We find export business fairly good. We are shipping largely to Europe and have had a satisfactory business all through the war. There was a big demand for tractors for their greater production campaign in Great Britain. In that business it is largely a question of giving the people what they want. Their style of implement is very different from the Canadian demand, particularly in plows and cultivating tools. The mouldboard of their plow, for example, is different from the Canadian. The Canadian tractors are very acceptable to them and ours received the highest award at Dublin Fair. Before the war, the tractor plow was practically unknown there, but now there will be a big demand for it.

"Our business is about one-third in Eastern Canada, one-third in the West, and one-third export. In regard to the latter, we have not asked the Government to do anything for us, but have acted on our own initiative. We anticipate a good export trade, and are shipping twenty-one cars to England alone in the next ten days. If Canadian manufacturers want to do an export business they must follow it up personally, as they can then get first-hand information which they cannot get in any other way."

The Damage Done by the Strike

That the strike of the metal workers in Toronto and some of the other industrial centres has set business back the best part of a year is an opinion that is freely expressed in trade and business circles.

"Two weeks before the strike came there was a noticeable improvement in the steel trade," stated Mr. F. C. Brunke, manager of the U. S. Steel Products business in Toronto. "Buying was commencing then on a more generous scale, and there was a return of confidence in the stability of prices that had been absent for a long time. It seems likely that the strike will be settled, and work begun again, but the trouble is that the mischief has been done. Structural work, for instance, is off for the season. As a general thing structurals are put up in the building season, leaving a great deal of interior finishing to be done in the winter. There will be none of that work this winter, as it will hardly be possible now to place business at the mills and get structurals erected for winter completion."

There have been many instances, according to Mr. Brunke, to show that unfavorable events have been plentiful enough to impede the return of normal conditions in the steel market. "Following the signing of the armistice," he remarked, "many of the consumers were in doubt as to what lines to turn to, and even yet there are cases where this same state of mind prevails. 'Waiting' seemed to characterize everything during the first two or three months of the year, and there were several bank officials who came out about then with decidedly pessimistic interviews, which did not tend to improve matters at all. Then toward the end of February the talk of price-cutting began to disturb the market, and every rumor that came out tended to make the buyer of steel think he was making a serious mistake in going into the market. The automobile, stamping, forging and agricultural industries were the first to show signs of recovery, but of course, many of them were covered on their wants by yearly contracts. The month of May also saw the eyes of Canada turned to some extent to Washington to see what would be the outcome of the squabble between the steel mills and the U.S. Director-General of Railroads, who refused to recognize the fixed prices. The impression seemed to gain ground that this move was going to let prices drop to a very noticeable extent. A little survey of the situation would have shown the impossibility of this, but it all helped to hold back the volume of business that should be expected from Canada. It was just at this juncture, after the Washington affair was settled, that there was an improvement. For instance, we were ready to close a deal for the supply of raw material to a firm that was going to make automobile rims in Toronto. It would have been a nice business for the city, but the strike came and the promoters of the business simply cancelled everything. What has happened since then is fresh in the minds of all who have followed the trade.

"Against this, there is an improvement in the buying. During the month of July we booked one order for 15,000 tons, the largest single order since the signing of the armistice. It is particularly unfortunate that Canada has had the amount of labor unrest that has occurred this year. The people of United States take a greater interest in this matter than most people suppose. They watch these events very closely. The Republic has not had anything like the trouble that has been found in the Dominion since the conclusion of the war."

Mr. Brunke, in conclusion, pointed out that the steel trade in United States was in splendid shape, and that in several lines the mills were practically out of the market, being filled to and beyond capacity for months to come. This is especially true of the pipe mills, and semi-finished branches. Prices are firm, in some lines with a higher tendency. It is his opinion that nothing whatever is to be gained by staying out of the market in expectation of lower values.

U.S. Firms Coming to Canada

The future of Canada, industrially, seems to look bright to the outsider, judging from the number who are looking across this way from the other side of the border. Mr. C. W. Kirkpatrick, Commissioner of Industries and Publicity for Hamilton, informs CANADIAN MACHINERY that there is a very pronounced increase in interest among our neighbors regarding Canada. There have been scores of inquiries, and there have been seven new industries from the United States located in Hamilton this year, including the following: Hoover Suction Sweeper Co., of North Canton, Ill.; Beaver Motor Truck Co., Chicago; Quaker City Chemical Co. (a branch of O. F. Zurn & Co., Philadelphia), oils, greases, finishing, etc; Gerard Wire Tie Co., New York (this company is incorporated for $400,000 in Canada); Lynat & Co., of Philadelphia, hat linings.

"The prospects for the future are extremely good," says Mr. Kirkpatrick. "We have at least one hundred United States concerns now negotiating for locations in Canada. They are feeling their way now, with a view to locating within the year. The unsettled condition of the labor market is keeping them back somewhat. Thev are also waiting to see what the preferential tariff will be. If it is high, there will be a great deal of manufacturing done in Canada for export. The Hoover Sweeper Company came to Canada for that reason. They expect

an increase in the British preference. They were not looking to the local market.

Freedom From Strikes

"One thing that has helped us this year in Hamilton has been the freedom from strikes. I attribute this largely to the fact that the men own their homes and are, therefore, more contented. There has been no Bolshevism and no strikes this spring of any account. The manufacturers and labor leaders here are entitled to a great deal of credit for the way they have handled things. After the war they got together and discussed the situation in an informal way, and the factories were readjusted to meet whatever conditions might arise. Foreigners were gradually weeded out and their places taken by returned men. The foreigners had been reaping a harvest. They drifted away. When one was dropped from one factory he was not taken on at another. The foreign population in Hamilton to-day is not more than half what it was a year ago.

"The outlook here is very, very good; and if labor conditions become settled I think 1920 will be one of Canada's big years. The prospects for the coming winter are not so bright, but I hope that new industries coming in will be sufficient to absorb the surplus labor on the market in the fall. By that time the soldiers will have exhausted their gratuity and will want to go to work; and outdoor labor also will be looking for winter work inside. Moreover, manufacturers do not feel like taking future orders, owing to the uncertainty of conditions. But when we get through the winter I think everything will be all right.

"We are getting a good many inquiries from Great Britain for locations, and the first big industry came this year—Porritts & Spencer, Bury, Eng., makers of commercial felts, which are chiefly used in paper making plants. They make blankets also. They think Canada will be the paper-making country of the world in the future, and that they will find a market here for their whole product. They will export to Japan from here. The plant is a million dollar one and employs 500 hands. There are many inquiries from Great Britain, both direct and through their chambers of commerce."

Mosquitoes two million years old.—Writing on the probable antiquity of mosquitoes, as shown by the geological record, Prof. T. D. A. Cockerell, of the University of Colorado, states that the oldest forms positively identified as belonging to the genus Culex or other genera of the mosquito family have been found in Eocene rocks, and are probably about two million years old. A form known as Culex damnatorum was described by Scudder from the Green River beds of Wyoming. Another Eocene species has lately been discovered by Mr. D. E. Winchester, of the U.S. Geological Survey, near Cathedral Bluff, in western Colorado, and is to be called Culex winchesteri.

Experimental air-sounding apparatus has been installed by the British Air Ministry on a 10,000-ton transatlantic cargo boat as another item in its after-war flying programme. The Ministry hopes to make the experiment a valuable preparation for transatlantic flying, and also a thorough test of the four appliances used: Winch, wire, kite, and meteorograph. Two winches are used, as a matter of fact, one at the ship's bow and one at the stern, thus allowing the kites to be flown from either end to avoid entanglement with the rigging. The mooring cable, which will rise five miles into the clouds, is of fine steel, very similar to marine sounding cable. The kites themselves are collapsible and made of fine linen and bamboo in two types, the larger measuring about 8 ft. by 6 ft. And finally, the meteorograph, the brains of the apparatus, consists of a revolving drum on which pen points register variations in humidity, pressure, and velocity of the air. When actually making soundings, this instrument will be towed four or five miles above sea level in the bigger box kite, while the small pilot kite will fly 400 ft. nearer the ship.

Valued for its weather-resisting qualities, galvanized iron or steel has long been produced by dipping sheets of the metal into molten zinc, which deposits itself as a coating of small crystals or spangles. Occasionally, however, sheets have been produced with large spangles which, it was found, improved both the appearance and the non-corrosive qualities of the product, and hence increased the price it would bring. So one plant has raised the value of its output by treating high-grade molten steel with an alloy containing titanium before rolling it into sheets and subjecting it to the zinc bath. It is claimed that 75 per cent. of the treated sheets emerge from the bath with the large spangles desired.

Out of the war shortage of tin has come a new and successful substitute for babbitt as a bearing metal. It is composed almost wholly of lead, hardened by an electrical process. Its high manufacturing cost is more than compensated for by the low market price of lead compared with tin. The new metal shows a tensile strength of 13,000 lb., the figure for genuine babbitt being 11,000; and an elastic limit of 11,525 lb. as against 10,000 for babbitt. Its friction factor is very low. With a shaft running at 400 r.p.m. and a load of 1,000 lb. per sq. in., 150° was the highest temperature reached by the bearing.

Across 11 miles of rough country near Pittsburgh, Pa., is being constructed what is probably the largest gas line in the world. It will have a maximum diameter of 40 in., enabling it to convey 70,000,000 cu. ft. of gas daily from a by-product coke plant to three steel mills.

The Fiddler Presents His Bill.

The Handling of Material in the Small Shop

The Solution to the Handling Problem is Often a Very Simple Matter if Thought Out Seriously—Here is One Example Where One Problem Was Very Easily Solved

THIS article does not pretend to cover the requirements of the large size, up-to-date plant, but rather applies to the small shop which cannot afford an elaborate crane system to handle their product from the shipping door or platform.

In a small shop, such as we wish to bring the readers' imagination, there is generally a monorail crane installed right down the centre of the shop. This crane is supposed to handle all work within the confines of the shop, irrespective of its position. This usually means that if the shop is rather wide, rollers are placed under the work, when the work is skidded over until it comes within reach of the crane.

They never seem to realize what an inconvenience this is nor the fact that good money is going to waste every time they adopt this near-sighted principle, and so they go on from day to day, merely making ends meet with only a fair profit.

To suggest an improvement is the start of a storm for you will, ten chances to one, hear them say that their shop is not large enough to warrant the expense of a better crane system.

They usually start to talk of the expense of an overhead crane, when often, even if they did desire to place such equipment in their shop they would find themselves without the necessary head room. Briefly they are stalling for wind and excuses and so they plug along under this load.

It never seems to enter their mind that even a monorail system can be installed to cover at little expense the entire floor area without the necessity of using the roller skids.

A PROBLEM IN LIFTING AND SHIFTING WHICH IS TOO OFTEN NEGLECTED.

A little careful thought, together with suggestions from the crane manufacturer, will often bring surprising results in efficient handling, yet the penny-wise, pound-foolish policy continues to exist.

This policy seems to be especially noticeable when it comes to the shipping department in the small shop. Usually the complete department consists of a door instead of a platform, and no mechanical means of transporting ma-

terial from the shop to wagon or vice-versa is supplied.

When the wagon is drawn up at the door this is the signal for three, four and sometimes six men to go out to the door and aid in the lift from the wagon to the door level. This distance is generally at least two feet, sometimes more, and as the material is often quite heavy the result is that the men return to their work in none too good condition, not to speak of the sore spot it always leaves in a man to think that, in a way, although he is employed as a tradesman, yet he is from time to time called upon to do the work of an ordinary laborer.

Another point not considered is the waste of good time. If the day is fine the men as a rule have a little chat, perhaps a smoke if the management is not too strict, and so the expense item mounts up. Year in, year out, this goes on, while if a system of some type was installed the wasted time alone would soon pay for the equipment.

A typical example is illustrated at Fig. 1. Here we see the old, old story. The small shop, with its side shipping door leading into the alleyway, the motor truck has drawn up with the box. That is usually the signal for the foreman to shout, 'Oh Jack, Bill, etc., etc., come and give us a lift, will you?"

But in this case the solution was different and sensible. This firm got tired of the lifting by hand stunt, so rigged up a Herbert Morris 1½ ton crane as shown at Fig. 2.

Of course the problem was solved so easily that no comment is necessary, in fact the solution was self-apparent from the very first. The only difficulty seems to be to convince the owner of the small shop that by installing such a scheme he will save money in the end.

So this article was prepared almost, we might say, as as illustrative moral lesson that it pays to handle your goods mechanically.

HERE IS THE SIMPLE SOLUTION THAT THE MORRIS CRANE CO. INSTALLED.

The Government of India has appointed G. T. Barlow, chief engineer for irrigation of the United Provinces, and J. Mears, electrical adviser to the Indian Government, to inquire into the country's water-power potentialities. They will personally inspect water-power sites and decide which ones are worthy of detailed investigation. This will be the first step in a thorough hydrographic survey in preparation for the eventual development of India's power resources to their fullest extent. The supply of coal is limited, and in view of the great industrial expansion expected in the next few years the investigation of alternative sources of energy has become a question of national importance.

That flowers sleep is evident to the most casual observer. The beautiful daisy opens at sunrise and closes at sunset, whence its name "Day's eye." The morning glory opens with the day. The "four o'clock" awakes at four o'clock in the morning, but closes its eyes in the middle of the day, and the dandelion is in full bloom only while there is strong light.

The Leaside Shops of Canadian National Railway

CAR SHOPS AND TRANSFER TABLE

Forge, Locomotive and Car Shops With Capacity of Ten Engines and Ten Cars Per Month—Round House Also is Provided With Ten Stalls—Interesting Machines in Locomotive Shops

By T. H. FENNER, Associate Editor

TO the citizens of Toronto the name of Leaside has become familiar during the past strenuous years. Though its appearance and the natural features of its approaches are of a bucolic rather than industrial cast, it has been associated with industry of a most concentrated kind. The Leaside Munition Co., one of the most efficient plants under the direction of the Imperial Munition Board, were busy turning out enormous quantities of shells of various calibres for a long period. Close by was the aviation camp of the R.A.F., and from this camp many courageous and expert flying men went forth to battle with the Hun.

Now that these activities are happily no longer required, it might be thought that Leaside would be allowed to sink back to its pastoral calm, disturbed by nothing but the searcher after a lot to build his house on. This is not the case. Leaside having once been the home of national enterprises is perpetuating its good work. On its sandy soil has been reared a collection of workshops, owned by the people of Canada, to care for and rejuvenate the locomotives and cars of Canada's National Railway.

The site has many features to recommend it as a railway shop location. Within about three miles of the end of the Yonge Street car line of the Toronto Street Railway, about one and a half miles from the Metropolitan car lines, with good roads leading to it, and directly on the main line of the Canadian Pacific Railway, it is easily approached. It is near a large centre of population, from which to draw its labor, and also possesses the advantage of having space in which to expand as expansion becomes necessary. There is plenty of land available for home building, and there can be no doubt that the coming of the railway shops will mean the building up of a residential district in the not far distant future. As other industries are locating in the neighborhood, the housing development is altogether likely.

At the present time a portion of the working forces are being accommodated in temporary quarters, bunks and beds fitted up in the round house building. When the round house is put into operation it will be no place to woo Morpheus, the snore of the human being is of but tiny proportions compared to the grunt of a tired locomotive.

The General Layout

The photograph showing the exterior of the buildings gives a good idea of their arrangement and extent. On the extreme right, outside the round house, is a turntable connecting with the main line and with the ten tracks leading up to the round house stalls. Directly behind the round house is the power plant, where the electric power, compressed air, heat and light are generated.

The central building is the office and store space. The office building is a three story erection, large enough to house the full clerical and executive staff. The portion of the building devoted to the stores is directly behind the office. It is of two storeys, and is equipped with a shipping platform extending the full length of the building. The tracks are depressed sufficiently to bring the platform of the cars level with the platform of the store room, to facilitate loading and unloading.

To the left of the office building is the locomotive shop, wherein is contained all the varied machine tools necessary to the work to be done. One side of the shop is devoted entirely to the locomotive pits, of which there are ten. Directly behind the locomotive shop is the transfer table, which is used for placing locomotives and cars respectively in their desired position in the shops. The car shop is behind the transfer table, and our illustration shows this plainly.

The forge shop is situated in front of the locomotive shop and directly in line with it. Narrow gauge tracks are laid in the forge to provide easy handling of material and between and through all shops the standard rails are laid.

On the ground between the shops and the main line a large sorting yard is being laid out, about ten sets of tracks being now in position.

The Forge Department

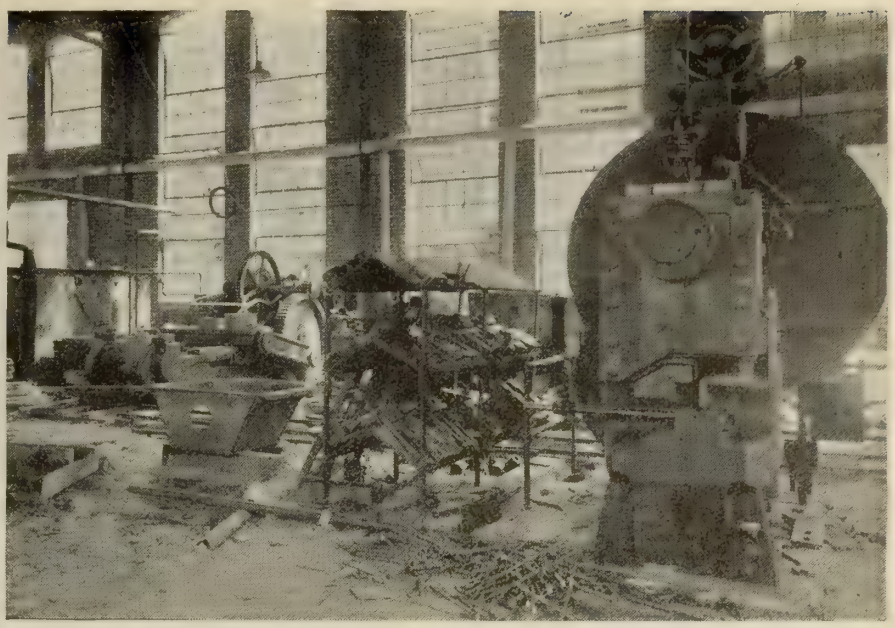
In a locomotive repair shop the forge department is the keystone. This is where the raw material, that will eventually become accurately machined and fitted parts of the great machine is re-

ROUND HOUSE, OFFICE, LOCO SHOP AND FORGE

eived. Here it is heated in oil and coal urnaces, hammered and beaten by hand nd steam power, crushed in a giant uildozer, to finally emerge as connect- ng rods, side rods, brackets, bolts, prings, spring bands, etc. Some pieces, uch as springs, are finished in the forge, while other parts are sent to the locomo- ive shops for machining and fitting.

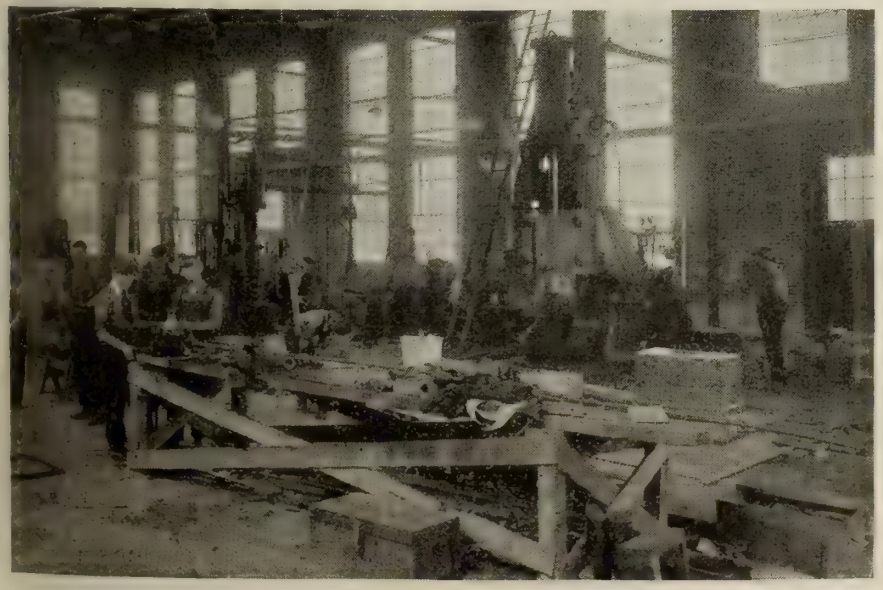
To perform all these operations quite number of tools are required, and killed operators to work them. The hop at the time of writing was not uite complete, some machines not hav- ng been put up as yet. However, work as being carried on briskly, and the wo views of the shop shown in our illus- ration give the reader a good concep- ion of the arrangement.

Down one side of the shop are the coal ires and hand anvils. The centre is de- oted to the hammers, and the other ide to the power machines and oil fur- naces. Entering the shop at the west nd, one sees the tool smith busily en- aged in fettling chisels and sets, etc., at fire on the left. Occupying the centre s a 300 lb. Beaudry motor driven ham- ner. This hammer, capable of deliver- ng blows rapidly, is a very useful tool or such jobs as small welds, making olts, pins, and light work of all descrip- ions. To the right of this is a small oil urnace in connection with a centre unching machine. The work done here s to make a pop in the flat leaf springs, hich serves the purpose of keeping them n alignment in the built-up spring. The it on the one spring fitting into the pop n the succeeding one. Close by this is a 6 in x 12 in. spring bander, working ith compressed air, its purpose being o press the heavy bands onto the springs hich hold the laminations together. his machine is made by Joseph T. Ry- rson, Chicago. Coming down the shop e next find an 8 in. x 1½ in. Bertram hearing machine, motor driven, which is lainly seen in the illustration. Against he wall, and not visible in the photo- raph, is a 2 in. Ajax bolt forging ma- hine, with its accompanying oil furnace. The 8 in. bulldozer can be plainly seen in the illustration, the heavy spur wheel and connecting rod conveying a good idea of the power of this machine. Alongside of the bulldozer is an oil fired furnance, for heating the work. On the occasion of the writer's visit the spring smith was using this furnace to temper and set the leaves of the laminated springs. The photograph taken from the other end of the shop shows the steam hammer, with the blacksmith's fires in the background. The large hammer in the foreground is a Niles-Bennet-Pond 3500 lb. hammer, while the smaller hammer in the centre is a Bertram 1500 lbs. The shop is lofty and well lighted, and there was a notable absence of the gas fumes that too often hang around a forge.



FORGE SHOP, SHOWING SHEARING MACHINE

This is really the foundation shop of a locomotive repair works, occupying the same relative place as the foundry would in a stove factory. As can be seen from the illustrations, ample space has been arranged around all the machines. The bench seen is, of course, only in use while the installation is being made.



FORGE SHOP, SHOWING LARGE HAMMER

The Locomotive Shop

From the forge the logical step is to the locomotive shop, pausing on the way to observe the huge stock of tires piled outside. One also notices the plate rack, where the boiler plates are stored. This is situated at the end of the building, where the least amount for handling will deliver them into the boiler making section of the shop.

Entering the shop, the thing that dominates the eye is the array of locomotives in different stages of dismantlement, occupying the whole of one side of the shops. There is something almost pathetic in their helpless state, contrasting so strongly with the idea of enormous power that a railroad engine usually conveys. There they stand, supported on huge blocks, with their natural means of locomotion torn from under them, while skilful locomotive doctors tear out, to replace in new strength, their innermost vitals.

These locomotives are up for what is known in the language of the road as a "general." Its full description is general overhaul. After a general, a locomotive is good, with the exception of minor running repairs, for a working stretch of from two to five years. The length of time will, of course, vary with the exactions of the service in which it is engaged.

When a locomotive is brought up to the shop for a general overhaul, it is first put over the jackpit. This pit contains a 200 ton electric jack made by the Whiting foundry. The uprights shown in the illustration form supports and guides to the two heavy cross beams, which are raised and lowered by the revolution of the heavy square threaded screws shown.

The locomotive being placed over the pit, the jack is raised till the frame of the engine is supported by the cross beams. The main bearings are then

VIEW FROM GALLERY IN LOCOMOTIVE SHOP

slacked off and the jack is elevated until the body of the locomotive is clear of the trucks. Side rods, conecting rods, eccentric rods, are all disconnected from the driving axle before the lift is made, leaving everything clear for the trucks to be run out.

The body of the engine is now resting on the jack, and in order to free the pit for another locomotive to come in, wooden blocking and low, strong trucks are brought into use. These trucks are run in on the rails and strong blocking built up on them to the locomotive frame. Lowering the jack, the weight is taken on the blocking. The trucks, carrying the locomotive, are then run out on to the transfer table, shown in our illustration. This table performs the service of placing the engines on any one of the ten tracks available. The transfer table carries its burden up to the required track, and permanent blocking is built up from the ground, and the frame wedged up till the weight is off the trucks. These can then be removed and used again for the same purpose on other trucks.

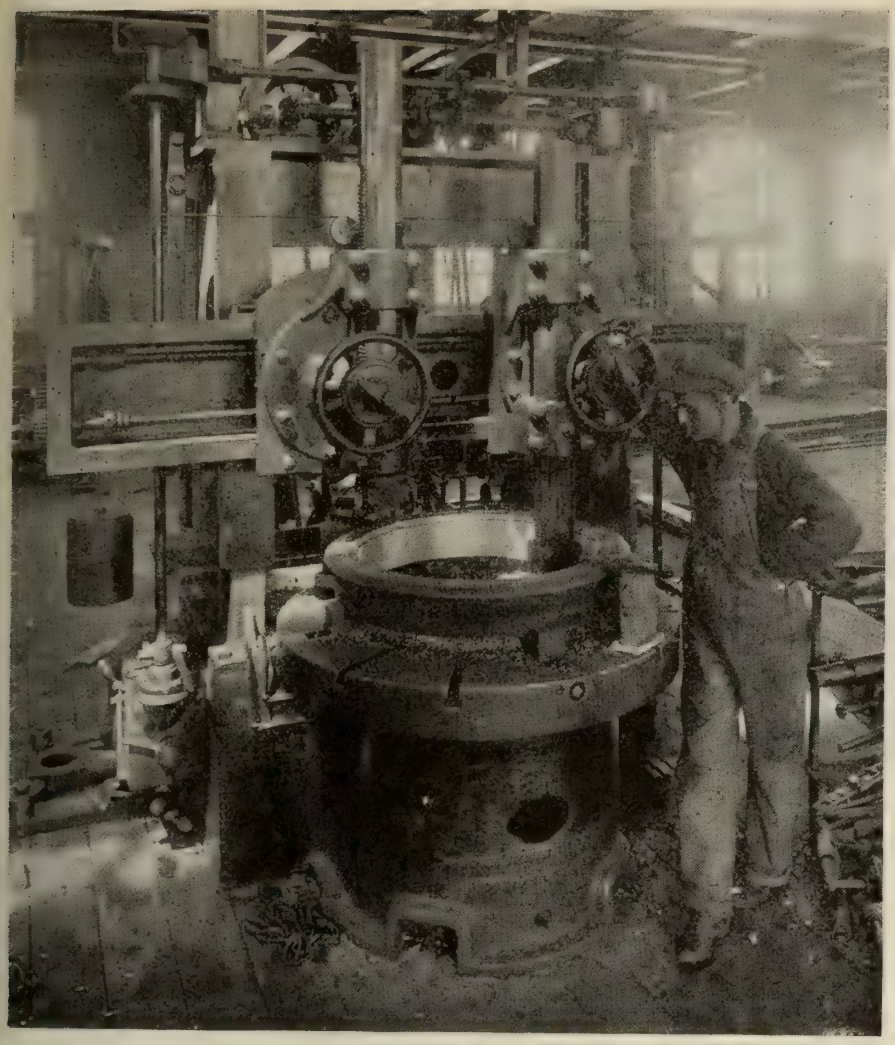
When set up on the permanent blocking work is commenced right away. The boiler will be examined thoroughly and all necessary repairs made. These will consist generally of new stay bolts in fire box, building up of any parts wasted by corrosion with the oxy-acetylene or electric process, removing the boiler tubes, and after cleaning, welding new ends on, if the condition justifies, or if not, putting new tubes in. While these are out the shell will be cleaned internally. The superheater will be gone over thoroughly, and in fact every part narrowly examined.

The engine will be taken apart in detail, cylinder covers removed, pistons drawn, piston withdrawn, in some cases the cylinders dismounted from the engine frame, guide plates, crossheads, side rods and eccentric straps and rods all taken down and examined carefully. Connecting rod and side rod ends will probably require new bushings, cylinders need boring out, new pins fitted here and there. In connection with the cylinder boring, the wirter noticed a very handy rig in the shape of a portable boring bar, driven by compressed air, and bolted on to the engine frame.

The air pump for the Westinghouse braking equipment is dismantled, and overhauled, and all the piping and brake gear likewise. A galley running the full length of one side of the locomotive shop has half of its space devoted to air brake repair and testing. This is, of course, one of the cardinal features of train equipment, and must always be kept up to the highest efficiency. Our illustration shows nine locomotives in process of a general overhaul, and on the second one the tubes can be seen being removed from the boiler.

All three welding processes are in use in the shops. A large motor, which had suffered the misfortune of having its supporting lugs broken off, was being repaired by the oxy-acetylene process. The thermit method is also very much in evidence, and our illustration shows a good example of this style of welding. A portable electric outfit supplied by the

BOILER DEPARTMENT—SHEAR AND PUNCH



BORING OUT TYRES

Lincoln Electric Co., was also seen in the shop.

The Boiler Department

One end of the locomotive shop is fitted to deal with the boiler repairs. There is a tube welding furnace, and welding hammer, where the tube ends are removed.

The rolls for bending boiler plate are here, and a large Canada Machinery Corporation combined punch and shears. This machine, with the men engaged in punching a plate, is plainly shown in our illustration. There is also a double-headed Landis threading machine, where stay bolts, studs, etc., are made. There is also a Jas. Crossen plate shear, Cleveland horizontal punch, and a John Bertram horizontal boring machine.

The Engine Department

Walking up the shop one comes to the motor driven wheel turning lathe, another Bertram tool. This machine is provided with two face plates and two tool holders. The wheels mounted in their axle are centred on the face plates and are turned up simultaneously for the tire to be fitted on.

Close by are located the fitting benches and lathes, where the link motion is fitted up. The link motion, of course, is the valve gear, such as rods, quadrants, valve blocks, pins. This is comparatively light work, mostly for straight lathe operations. There are two "Perfect" engine lathes and one Walcot. There is also a Walcot shaper, which was being used for shaping sides of connecting rod end brasses. Coming further up we come to the heavier tools. There is a Bullard vertical turret lathe, which is employed on piston valve liner work, a Canada Machine Corporation planer, which can be seen engaged on a cross-head guide plate, and a borer of the same make, boring out connecting rod brasses.

A good example of the heavier machine work is shown in our illustration of the Bertram double headed boring machine.

The shop is here divided by a track, for bringing in material from the forge. Crossing over this, we come to the connecting rod, side rod and piston department. The chuck and bottom brackets for main bearing boxes are planed and slotted here also. The machines here are representative. One notices a Bertram shaper, C.M.C. slotter, lathe by the same makers, and a battery of three quick acting drill presses by the Superior Machine Co., Kokomo, Ind.

An American Tool Works motor driven lathe is in use for turning the pistons, rods, axles and such heavy jobs. The large piston rings are bored and turned on a Bertram double headed vertical borer. Another Walcot shaper and engine lathe and a Perfect speed lathe are here. Heavy bolts are made on a Hartness flat turret lathe.

There is, of course, a tire pressing machine of the usual type, but we were not fortunate enough to see it in action. This machine is also a Bertram.

In our illustration showing the locomotives a foundation form can be seen in the foreground. This is for a coach wheel lathe, which will be supplied by Bertrams, who are also supplying an 84 in. boring mill. The Canada Machinery Corporation is furnishing a 48 in. planer.

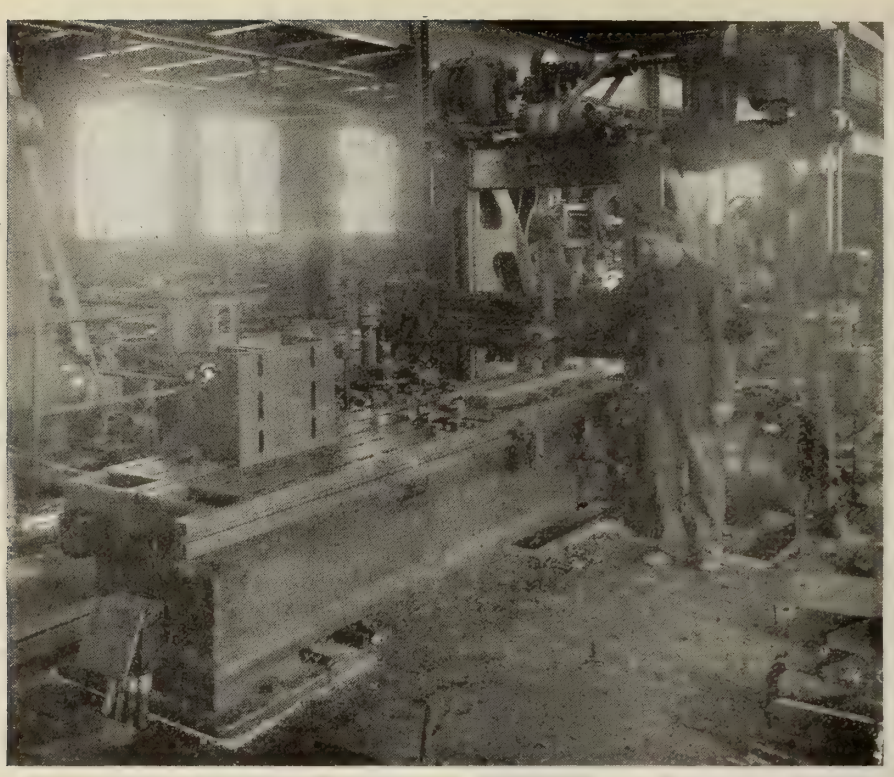
The locomotive shop is supplied by two Northern cranes, each of 15,000 lbs. capacity, and traversing the full length and width of the building.

The Car Shop

Leaving the locomotive shop regretfully, for there was much to interest the observer, and crossing over the transfer table, the car shop is reached. The tracks correspond with those of the locomotive shop, so that the transfer table is available for both departments.

One thing is noticeable immediately on entering the car shop. It is the excellent light available through the many windows and skylights. Light is, of

TURNING WHEEL RIMS



PLANING A GUIDE

course, a necessity here, where so much of the painting and decorating is done to the cars.

The cars that come to this haven are battered veterans. One with its vestibule all crushed in, reminds one of a broken nosed prize fighter. A second shows all one end badly burned up, probably due to an overheated cook stove, it being a dining car.

Most of the tracks in the shop are occupied, the cars on them undergoing repairs so extensive as to suggest in some cases rebuilding. The bodies are jacked up from the trucks and the trucks run out to have the wheels, frames, springs, etc., all examined and repaired. The body of the car is then gone over, all broken woodwork replaced or repaired, upholstery cleaned up, lavatory accommodation examined and renewed where necessary. Finally comes the painting and varnishing and then the car is ready to be put in service again.

A space is left at one end of the shop to accommodate the necessary woodworking machinery, which is similar to that in use in any establishment manufacturing cabinets, etc. All that is at present installed is a swing saw and rip saw. Ten cars a month can be received, overhauled and delivered when the shop is working at capacity.

The Power Plant

The power plant building is located at the rear of the round house, and is a one storey building with firing floor in the basement. The boiler room is situated at the end of the building, nearest to the main tracks, and on elevated track is provided leading to the concrete bunker. Cars of coal are run up this track, over the hatchway and dumped, thus saving any handling.

The boilers are of the Babcock & Wilcox type, four in number, installed in two batteries of 400 h.p. each. They are hand fired and fitted with Cyclone shaking and dumping grates. For returning condensation from the different buildings there in an installation of return steam traps, made by Geo. W. Cole Ltd. The pressure carried is 140 lbs. per sq. in.

The feed pump arrangements consist at present of three duplex outside packed Northey pumps, located in a pump room between boiler and engine room. Here is also the fire pump, which is of the usual underwriter approved type, made by the Canadian Allis Chalmers. It is 14 in. x 7 in. x 12 in., and has a capacity of 500 gallons per minute. There is also a condensing pump by Deane, Boston.

Ascending to the engine room level we find first the Ingersoll Rand unit, supplying the compressed air for the various shops. The capacity of this machine is 1,500 cubic feet of free air per minute, at a pressure of 100 lbs. per square inch. The cylinder dimensions are on the steam end, 14 inches by 24 inches, by 24 inch stroke. On the air side they are 22 inches by 13 inches, the stroke, of course, being the same. The speed of the machine is 170 r.p.m.

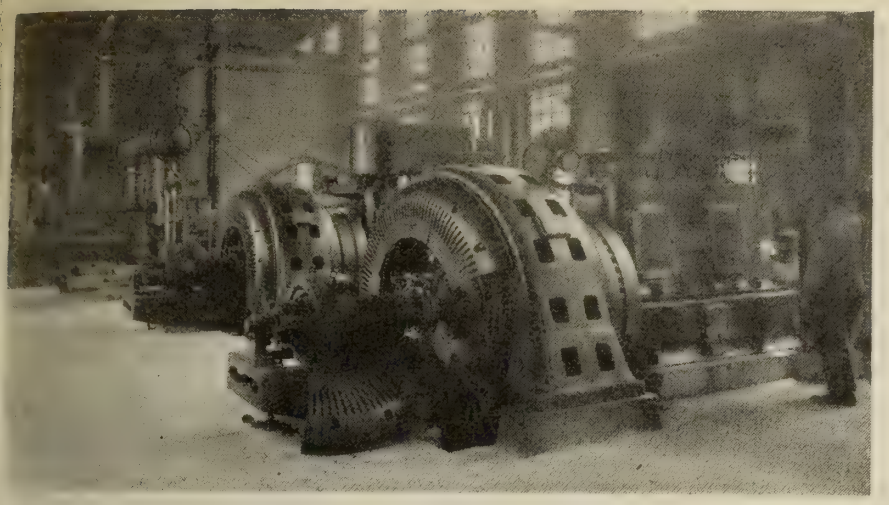
The electric generating units are two in number, and are alternating generators direct connected to vertical compound high speed engines. Both generators and engiens come from Old Country makers, the generators from Scotland and the engines from Lancashire.

The generators are manufactured by Bruce Peebles & Co., Ltd., Edinburgh, and are of the 2 phase, 25 cycle type, generating 360 k.v.a. at 375 r.p.m. The electrical pressure is 560 volts. The exciter for the field coils is connected on the generator shaft, and works at 30 volts and 130 amps.

THERMIT WELD ON LOCO FRAME

The engines are made by Brownet,

200-TON ELECTRIC JACK



DIRECT CONNECTED ALTERNATING GENERATOR

indley & Co., Patricroft, near Manchester. They are of the compound, ertical, high speed, enclosed type, work-ig at 140 lbs. pressure, and with forced ubrication.

For supplying direct current to the ariable speed motors, a C.G.E. motor enerator is installed of 185 h.p.

Tunnels are being constructed between he power house and the different shops o lay the steam piping, water and air ines. These are being carried at pres-nt on temporary trestles overhead.

The Round House

The round house is not really round, being constructed on an arc of a circle. There is, of course, a large turntable opposite, which connects with the main lines and the radial tracks leading to the locomotive stalls.

The house is divided into two sections of five stalls each, the total accommodation being for ten locomotives. This round house is not in use as yet, being occupied, as mentioned above, as a temporary hotel and store room.

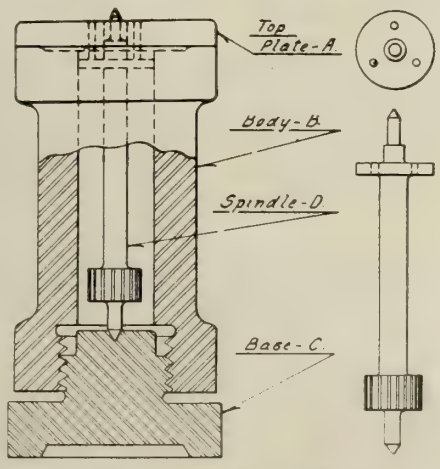
The shops as a whole will employ when complete and in full working trim about 700 men. A permanent industry of this kind must be of immense benefit to the district in which it is situated.

Later when the freight sorting yard is also in operation, Leaside will be an important point on the National Railway system, and will no doubt, engage in friendly rivalry with the Moncton shops for efficiency in their daily operation.

DRILL JIG FOR SPINDLE

The writer had a number of small gearing spindles to drill on the flange as per sketch. The spindles were part of a clock movement used in connection with electrical switchgear. The particulars of the jig are as follows:

A is the top plate made of cast steel, hardened and held in position on the body B with cheese, headed screws and dowel pins, the holes being too close together to allow separate bushes and thus dispense with the necessity of a top plate. The body B is of mild steel, screwed out at the bottom to take the base C and bored out to allow the spindle to drop into position for drilling. The base C is of mild steel, screwed to fit in the body B. As will be seen from the sketch, the base C has a hollow centre which locates the work and keeps it in position whilst being drilled. The screw on the base C is a coarse pitch and short, so that when the work is in the jig and the base screwed up, it just requires a couple of turns to lock it securely. I had intended making the



SECTIONAL VIEW OF THE JIG.

base and body in one piece and employing the same means of locking the spindle, as is used on the breech blocks of artillery, but abandoned it on account of the cost. The jig, as shown, proved very successful.

A certain American plan, which employs a considerable number of girls, were confronted with the problem that their female help complained that the men rushed and crushed them when making for the street cars in the evenings. The following notice was placed in a prominent position with splendid results: "Girl workers, comig in late, say they could not catch cars at the crosstown lines, because men from the plant rush the cars, and a woman might be badly hurt. Let's remember, fellows, that these girls are fellow-workers; some of them have to help support the family. Give them a chance and help them on the cars. It won't hold you back any, and it will be 'helping the other fellow' where it counts."

Since the beginning of the present year unemployment in Denmark has increased at such a rapid rate that it has come to overshadow all other problems. From a pre-war maximum of 50,000, the number of unemployed has increased until it now totals more than 63,000. The Government has been trying to meet the situation by the passage of laws for subsidizing labor union benefit funds, for establishing Government employment bureaus, and for lending money to communities in order to enable them to carry on public works. The Ministry of the Interior has called conferences between representatives of the trades unions and the employers' associations in the hope of reaching a solution of the problem.

A NEW USE FOR TRACTORS

Small tractors are proving of great value to the United States Government in drawing ashore their various seaplanes after their flights. This is a much handier method than wading in for them and pulling ashore, as was sometimes done. The field of usefulness for tractors of small build is practically limitless.

Peonage in Ecuador has recently been abolished by legislative decree. Prior to the passage of the decree, a peon was compelled to remain on an estate as long as he was indebted to the owner, a condition amounting virtually to slavery, since the owner could easily manage to keep the peon in a state of permanent indebtedness. The decree completed the emancipation of the peons by cancelling all their debts. A peon may now go where he pleases, work for whom he will, and enjoy equal rights with other citizens of the republic.

It isn't often that elephants are so numerous that they become a nuisance, but such is the case in a place called Addo Bush, near Port Elizabeth. The pesky animals will persist in spoiling all the farmers' efforts, and once in a while even get real wild and kill some people. The upshot is that the Government have decided to shoot them. This process, they figure, will take at least six months, and necessitate the erection of lofty observation towers. The younger elephants will be captured, if possible, and trained to haul logs in the forests, but the adults will simply be shot, and their meat consumed by the natives.

Getting Ready for the Shop Emergency

Every Well-Appointed Plant Must Have the Means to Deal Quickly and Efficiently With Any Mishap That May Be Encountered—How the Outfits Are Made Up

A FEW years ago when accidents occurred in the shop or factory intelligent first aid treatment was not possible. Training in first aid was lacking and equipment necessary for bandaging, treatment of wounds and burns and recovery from shock was in the majority of industries non-existent. Compensation costs, humanitarian motives and a growing appreciation of the necessity for avoiding loss to the individual and to the community have wrought an appreciable change, and today first aid, together with its more important corallary, accident prevention, is a very live topic.

Industrial accidents naturally vary in severity and in type with each industry considered, but, broadly speaking, may be classified as wounds and bruises, burns, poisoning and infection, electrical shock and those due to organic troubles particular to the patient himself. First aid appliances and remedies, then, should be ample enough and general enough in their nature to take care of practically all these features.

First Aid Cabinets or Boxes

For emergency work in the factory itself and where the factory is not of sufficient size to warrant a first aid room or hospital, cabinets or boxes are of much value and these should contain everything likely to be needed.

Bandages are an important essential, and several sizes should be included. Possibly the most used sizes are 2½ in., 1 in. and triangular bandages, and at least six of each kind should be on hand. The three-inch size is also frequently used.

Gauze and absorbent cotton are also very necessary, medicated gauze being especially useful. Several packages of each should also be kept on hand together with a spool of adhesive tape. The two-inch width is plenty wide enough and can be easily cut into smaller widths as required.

While at first sight safety pins may be considered an unusual part of first aid equipment, yet nothing is handier for fixing and fastening bandages in place.

Antiseptics should be carefully chosen for their efficacy and non-poisonous properties. Corrosive sublimate or bichloride of mercury should not be included, both on account of its poisonous properties and also of the frequency with which it may be purloined. Tincture of iodine, perhaps, is as useful as any, and hydrogen peroxide also comes in handy, while boracic acid makes one of the best antiseptics. Medical supply houses make a specialty of antiseptics for first aid work, and a number of excellent preparations are on the market, such as Triseptol, for washing wounds, etc., and Borofax, a borated ointment. One caution should here be observed. Never purchase ointments, etc., in jars, but always in collapsible tin tubes. The open jar may prove to be a dangerous source of infection, whereas in the tin tubes no infection from previous users need be feared.

Stimulants may be included to advantage and of these sal volatile, or smelling salts, and aromatic spirits of ammonia should always be on hand. Aromatic spirits of ammonia is especially valuable in case of faintness, and as a stimulant in case of shock from wounds, etc., if given with water. Ginger tablets are also of use.

Foreign bodies in the eye, when not deeply embedded, are most easily removed by means of oil, the oil being dropped into the eye under each lid and allowed to work itself out. Castor oil is excellent for this purpose and with it an eye-dropper and a package of camel's-hair brushes should be included.

With the above in a first aid kit should be included a pair of surgical scissors, a tourniquet for stopping the flow of blood, a first aid book, surgical needles and silk, and a pair of dressing forceps, a medicine glass and eye cup will complete the outfit.

The above list is quite complete and should be sufficient for the ordinary first aid kit. Space may some-

THE MASSEY-HARRIS CO. HAVE A WELL APPOINTED EMERGENCY STATION WELL FITTED UP.

times be saved by the use of compressed bandages and gauze, but while these may be used, compressed absorbent cotton has the very decided danger of possible infection from the operator's hands while being pulled out.

No mention has been made of remedies or first aid treatment for burns in the above. This, in some measure, is apart by itself as the likelihood of severe burns is not met with in all branches of industry. Where burns are likely to be encountered, carron oil or picric acid solution should always be on hand. Carron oil, an emulsion of limewater in linseed oil, forms an excellent and soothing first aid treatment, and at least a pint should be kept on hand with every first aid kit where burns are feared.

A precaution should be observed in its use. When a portion of the oil is used it is better to throw away the remainder and to replace it with a fresh sealed supply. This overcomes possible deterioration and infection of the old oil.

First aid outfits are usually put up by those making a specialty of their sale, in wall cabinets or tin boxes. The tin box for factory use is quite satisfactory and for small outfits a tin lunch box painted a good conspicuous red with a white cross stencilled on it is as satisfactory as any.

First Aid Rooms

While in the smaller factories and in the various departments of larger ones, the first aid kit meets many immediate needs, many companies are equipping first aid rooms for the employees where all treatment is given. And while in Ontario the Workman's Compensation Act requires service of this character in plants employing sufficient help, it is usually found that the equipment goes beyond the letter of the law, and is a credit in most cases to the factory where installed.

FIRST AID ROOM OF THE NORTON CO., CHIPPEWA. NOTE THE SCALES AND CHART FOR TESTING VISION.

The first essential is the choice of a well-lighted, airy room of sufficient size, centrally located and accessible. The walls should be painted in a light color, preferably a cream or white enamel, and made as attractive as possible. The floor, where much dirt and sand is liable to be tracked in, should be of battleship linoleum; hardwood marring and losing its finish too easily. Ample ventilation should be provided and windows and doors screened.

Equipment

Running water should be provided, hot and cold if possible. Some first aid rooms in addition to the usual wash basin of good size, are provided with a foot bath. A case in point is the first aid room of the Massey-Harris Co., Toronto, factory as will be seen from one of the illustrations.

An operating table should be provided. This need not have all the fixtures nor flexibility of those found in the operating rooms of hospitals, but should be strong and preferably made all of metal enamelled white.

A hospital cot covered with rubber sheeting over the bed clothes sometimes does service as a dressing table and is often found in addition to it. An instrument table is required. These tables are usually made up of a steel framework enamelled white and with plate glass or porcelain top and shelves. Their usefulness is seen in the illustration showing the Massey-Harris first aid room where bandages in glass jars, antiseptics and dressing basins are seen. Small instruments needed for ordinary accidents most likely to be met with are also kept on the table along with a tray of antiseptic solution.

Other fittings seen in this same room are a two-basin stand and an instrument and storage cabinet. It will be noticed that a small desk is also installed. This in itself is one of the most important features of the room, indicating, as it does, the necessity for careful records of every case no matter how small. Since records are necessary for the proper conducting of a first aid department, and since reports have to be made out to the Workman's Compensation Board, these two functions are combined and the clerical work minimized. In some factories and industries the report made out for office use and statistical reports differs only from the form required by the Board in being made out for all cases instead of only those coming under the Compensation Act. At the Massey-Harris plant Miss Cooper, first aid nurse, keeps a complete record of every case no matter how trivial the accident. This record is of material benefit where continued treatment is necessary.

In the treatment of burns medical practice, as developed by the war, has undergone great changes. The ambrine treatment devised by surgeons in France has worked wonders with cases heretofore considered hopeless. Burns which in the ordinary course of events would have resulted in hideous injuries are now healed up without a trace of scarring.

The treatment is simplicity itself. A mixture of parafine waxes mixed so as to secure a proper melting point in the original treatment were brushed on the injured surface and layers of gauze interspersed between applications. A recent development in this treatment does away with the use of a brush and the melted wax sprayed on by an atomizer which is particularly suited to the first aid station. Two types of these atomizers are in use, one a small one heated on an electric hot plate or other heater, and a larger size with a water jacket which insures even heating and keeps the wax hot longer. The J. F. Hartz Co., Toronto, handle a special burn dressing for use with these or other atomizers which was developed by Dr. Barthede Sandfort, a French military surgeon.

This compound becomes fluid at about 120° F., and is applied to the tissues at a temperature of about 140° F. to 150° F. When applied this dressing causes no incon-

venience but on the contrary relieves the acute pain caused by the burn.

The chief advantages of this treatment are in the ease in which the dressing may be removed without pain and without the tearing of newly-formed cells. Skin grafting is usually unnecessary.

In building up the dressing the wax is first applied, then a layer of gauze, more wax, gauze, absorbent cotton

EMERGENCY STATIONS APART FROM THE WORKS ARE ATTRACTIVE. THIS ILLUSTRATION SHOWS ONE BUILT BY THE TENNESSEE COAL, IRON AND RAILROAD CO. AT ENSLEY, ALA.

and gauze, thus building up a dressing which is mechanically strong.

Equipment and supplies for a first aid station will, of course, include all that has been mentioned for the small shop kits or cases only in a more complete fashion and in greater quantities. Other items which are usually found are hot water bottles, scissors, tweezers, artery forceps, etc. A more varied supply of drugs is found including laxatives, salines, such as citrate of magnesia and sodium phosphate. Mouth washes, nasal sprays, A. B. S. & C. tablets, etc. Stretchers are important and it is often a wise plan to have a number located at convenient points in the shop.

Accident Prevention

Accident prevention has largely outgrown the "Safety First" movement in which it largely had its origin and to-day the display of danger signs is only one phase of the work. While these in themselves are excellent and necessary, it is better still to eliminate as much as possible the occasion for their use. The elimination of hazards and the intelligent education of the employee in the exercise of care both for his own sake and for the sake of others is recognized as being of far more value.

Two heads are better than one and the most effective means of securing the interest of the employees and also the elimination of positive sources of accidents is to put it up to the employees themselves.

Companies having to do with the generation and distribution of electrical power are keenly alive to the necessity for accident prevention and first aid work, not that accidents are more frequent, but that they are more frequently severe and affect persons other than those causing them. A number of excellent organizations have been started for the prevention of accidents by these companies and one which is applicable to general manufacturing is herewith described.

In the first place about 75% of all accidents are due to the man himself, not, perhaps, entirely to his carelessness but to his deficient interest in their prevention. Five per cent. are due to the deficient guarding of machinery, live parts of electrical apparatus, etc. This also includes the accidents due to the removal of guards while working on a machine and their not being returned. Twenty per cent. of the accidents occurring are due to purely accidental causes over which no control or very little can be exercised. These proportions are those obtained by only one company, but may be taken as indicative of industry in general. The most striking lesson to be drawn from these figures is the large percentage of accidents due to the personal factor or the man himself. To effectively diminish the toll taken by industrial accidents it is, then, necessary to interest the man himself at the same time as provision is made for the elimination of the mechanical features of a plant tending to cause accidents.

The system worked out by this firm may be of some interest, and in its working out valuable features worthy of note are evident.

Organization was placed directly in charge of an outside engineer who made it a specialty. In addition to the preliminary work of organizing he has been retained to act in an advisory capacity, and is in attendance at every meeting of the various committees formed. Seven sub-committees were formed, each one representing a particular department or group of departments when they were of small size. The members of each committee were appointed to serve about six months by the head of the department who was also a member, permanent, and who acted as secretary. The chairman of all the sub-committees formed a central committee with more authority, and to whom questions of a responsible nature were referred. An executive committee, consisting of the higher members of the executive staff of the organization, was also formed. The members of the various sub-committees were chosen in such a manner that each represented between 10 and 15 employees. A general secretary and supervisor who served on all committees was very necessary to the co-ordination of the work and to its smooth operation.

The various sub-committees meet once a month and have authority to pass on all matters of safe practice which do not involve the expenditure of money. Suggestions are encouraged from members of the various departments and these are taken up by their sub-committee approved of, rejected or, if of sufficient importance, referred to the central committee.

The central committee is competent to obtain results by the expenditure of money in maintenance work. Recommendations involving expenditure chargeable to capital account, or questions involving radical changes in design or policy are referred to the executive committee or council for their approval.

Recommendations are encouraged from everybody and

LUNCH BUCKETS CAN BE WELL ADAPTED TO EMERGENCY KIT PURPOSES.

each suggestion received is numbered. The number consists of first the number of the sub-committee in which it originated, followed by a dash and then by a serial number which only applies to these suggestions from the sub-committee in question, thus 7—27. Persons originating suggestions which have been put into practice or

have been approved are thanked by a personal letter from the management of the company.

Meetings of the various committees are held once a month in the company's time. Business arising out of the previous meeting is dealt with first and then any suggestions for the elimination of hazards, bettering working conditions, etc., are dealt with, and either acted upon, held up for investigation, or are passed on to the next higher committee where it comes within their jurisdiction.

Every accident is discussed by the proper committee and if possible its cause ascertained. Where possible a remedy is suggested which will eliminate similar accidents in future. The remedy, however, may have to do with more care on the part of the employee, in which case the recommendation is worded to that effect and has the effect of making others more careful.

All accidents, no matter how trivial, are reported and a form similar to that required by the Workman's Compensation Act is used.

The central committee receives a report from all subcommittees and is thus kept fully informed of the activities of all departments. One very important feature of the work is seen in the way accountability is determined. An accident may be due to faulty design, and the injured person entirely free from carelessness. Where such is the case the department responsible for the poor design is held accountable, not necessarily the one in which the injured man worked.

The above arrangement is developed into a monthly accident bulletin arranged somewhat as follows.

Section or Department.	No. of accidents in % This year.	Last year.	Days Lost in % This year.	Last year.
1	10	10	5	10
2	15	15	10	5
3	10	10	10	15
4	15	15	30	15
5	25	15	20	10
6	10	25	10	20
7	15	10	10	10
	100%	100%	100%	100%

The figures used are illustrative only and do not represent actual results.

It may be mentioned that in this present case only two accidents occur in each month in which a day or more time is lost, out of a total staff of about five hundred.

It may be argued that many of the suggestions would be impractical and perhaps even foolish. This is far from the truth, for out of all suggestions received, 72 per cent. have been adopted in their entirety and only about five per cent. absolutely turned down. This is a remarkable showing and well attests to the soundness of the scheme.

THIS ILLUSTRATION SHOWS AN EXTREMELY WELL-EQUIPPED EMERGENCY STATION INSTALLED BY THE FEDERAL SHIPBUILDING CO. AT KEARNEY, N.J.

STEEL FURNITURE ENAMELLED WHITE HAS AN ATTRACTIVE APPEARANCE, AS WELL AS BEING SANITARY. THIS EMERGENCY STATION IS EQUIPPED BY THE AMERICAN STEEL AND WIRE CO.

Many of the suggestions have involved considerable expenditure and the number of things brought to light is truly surprising.

Plans for a tunnel under the English Channel, discussed so frequently during the last sixty-odd years, are now on the verge of materialization. It is announced that England and France are in perfect accord on the subject, and that war experiences have robbed its opponents of most of their contentions. From an engineering standpoint no serious difficulty is anticipated; through the impervious gray chalk underlying the channel bottom, electric drills will doubtless find easy and rapid passage. The plan calls for two 20-ft. tubes, side by side, connected at short intervals by cross openings. A drainage tunnel underneath disposes of seepage water. At the centre of its length the tunnel dips to its lowest grade for one mile, constituting a water lock which could be flooded from the shore in case of military necessity. The total length from near Dover to a point between Calais and Boulogne will be 30 miles, of which 22 will be 95 to 175 ft. below sea bottom. The channel's greatest depth over the proposed course is 180 ft. Estimates allow five years for completion, at a cost of $100,000,000. Electric trains will make the passage in 40 or 45 minutes, giving England direct access by rail to all parts of Europe.

A curious method of casting iron pipe, devised by a Brazilian engineer, has proven quite successful and is being commercially undertaken in this country and Canada. A rotary, water-cooled cylindrical mold receives the molten metal, no sand being used. The iron, at very high temperature, is poured through a funnel into a trough, which is immediately introduced into the revolving mold and turned over. Centrifugal force distributes the metal evenly, and as graduated ladles are used, there is no waste. The finished pipe is withdrawn a few seconds after the iron is poured, coming out lengthwise quite easily. The walls of pipe so cast are remarkably thin and uniform, and tests indicate greater strength and closer texture than result from ordinary casting in sand. Many experiments in centrifugal casting of iron pipe have previously been tried, but did not prove commercially practical. The success of this system is attributed to the cold mold and the instant withdrawal of the pipe, which hardens as soon as poured.

Shellac is often used on gaskets to make them adhere to the metal surface while assembling. Gaskets thus treated are rendered hard and brittle, and must be replaced when the parts are reassembled. Cup grease, smeared on the gasket, will serve the same purpose, and will keep the gasket soft and pliable.

Shop Transportation

HANDLING of Material Coming to Be Recognized as One of the Chief Factors in Efficient Shop Operation.

By J. H. MOORE,
Associate Editor, Canadian Machinery.

IN entering a subject of this nature, one cannot proceed with examples of shop transportation without just making it thoroughly clear what is meant by the term transportation. The meaning conveyed by this term is not confined to the moving of goods over considerable distances, but can be equally applied to the ordinary movements of shop routine.

It is a rather common occurrence to hear some executive remark that their plant is not large enough to warrant an investment in any form of shop haulage, but if they only realized it, the very fact that they are so prejudiced in their viewpoint may be the reason that their shop remains so small.

It may be a long stretch of imagination from shop haulage to automobile, yet for a moment let us consider the similarity. In the automobile field one can choose from the lowly and much abused flivver up to the various master sixes and eights in practically every style to suit the purse. The same condition exists in the transportation field to-day, for, depending on the size of your plant, there is a haulage system to suit your requirements.

It would be the height of folly for a small manufacturer to install an elaborate crane, trucking or conveyor system, but still that does not say he should remain out of the field entirely.

Let him weigh the matter carefully, study his own conditions with an unbiased mind, look around him and see what the other fellow has done, and then adopt whatever suits him best personally, in this way profiting by the experience of others.

But we hear him remark, "How can I best proceed to study this problem?"

The Total Cost of Production

Naturally the first question that arises in connection with a subject of this nature is how the total cost of production is affected by the methods employed in moving material within the plant, outside the plant, and, if necessary, to the freight termianl.

Ascertain how much time is consumed on actual manufacture, then investigate what time is taken up in handling. This applies to both the productive and non-productive forces. For instance a man at a machine might consume five seconds obtaining a piece of work, 2 seconds for the actual operation, and 6 seconds to dispose of the work. This shows that eight-tenths or 80 per cent. of this employee's time is consumed in handling.

From these observations it would naturally appear that in attacking this case in point, the handling time would be the big problem to overcome. Such an illustration as the above may seem exaggerated, but in actual experience it is often found that as high as 90 per cent. is lost by a careless system of handling.

IT IS OFTEN GOOD POLICY TO RUN THE FREIGHT CARS DIRECTLY INTO THE SHOP. THIS ILLUSTRATES THE PLANT OF WATEROUS ENGINE WORKS CO. AT BRANTFORD, CANADA, AND SHOWS THEIR METHOD OF MEETING THIS CONDITION.

To give a concrete example we quote the following case:

This particular operator, by the old system of handling, turned out 336 units of work each day, but by improving the handling detail alone, the operator turned out 584 pieces without any additional exertion in labor, proving that sometimes it is a very small matter which hinders production.

Another case showed that the cost of handling a particular product through a certain department was .59 per thousand pounds. By facilitating the handling of the productive operators alone, the cost was reduced to .12 per thousand pounds. From these two examples it is plain to be seen that the productive operator and his time of handling must be considered as well as the actual haulage cost.

What Equipment Shall I Use?

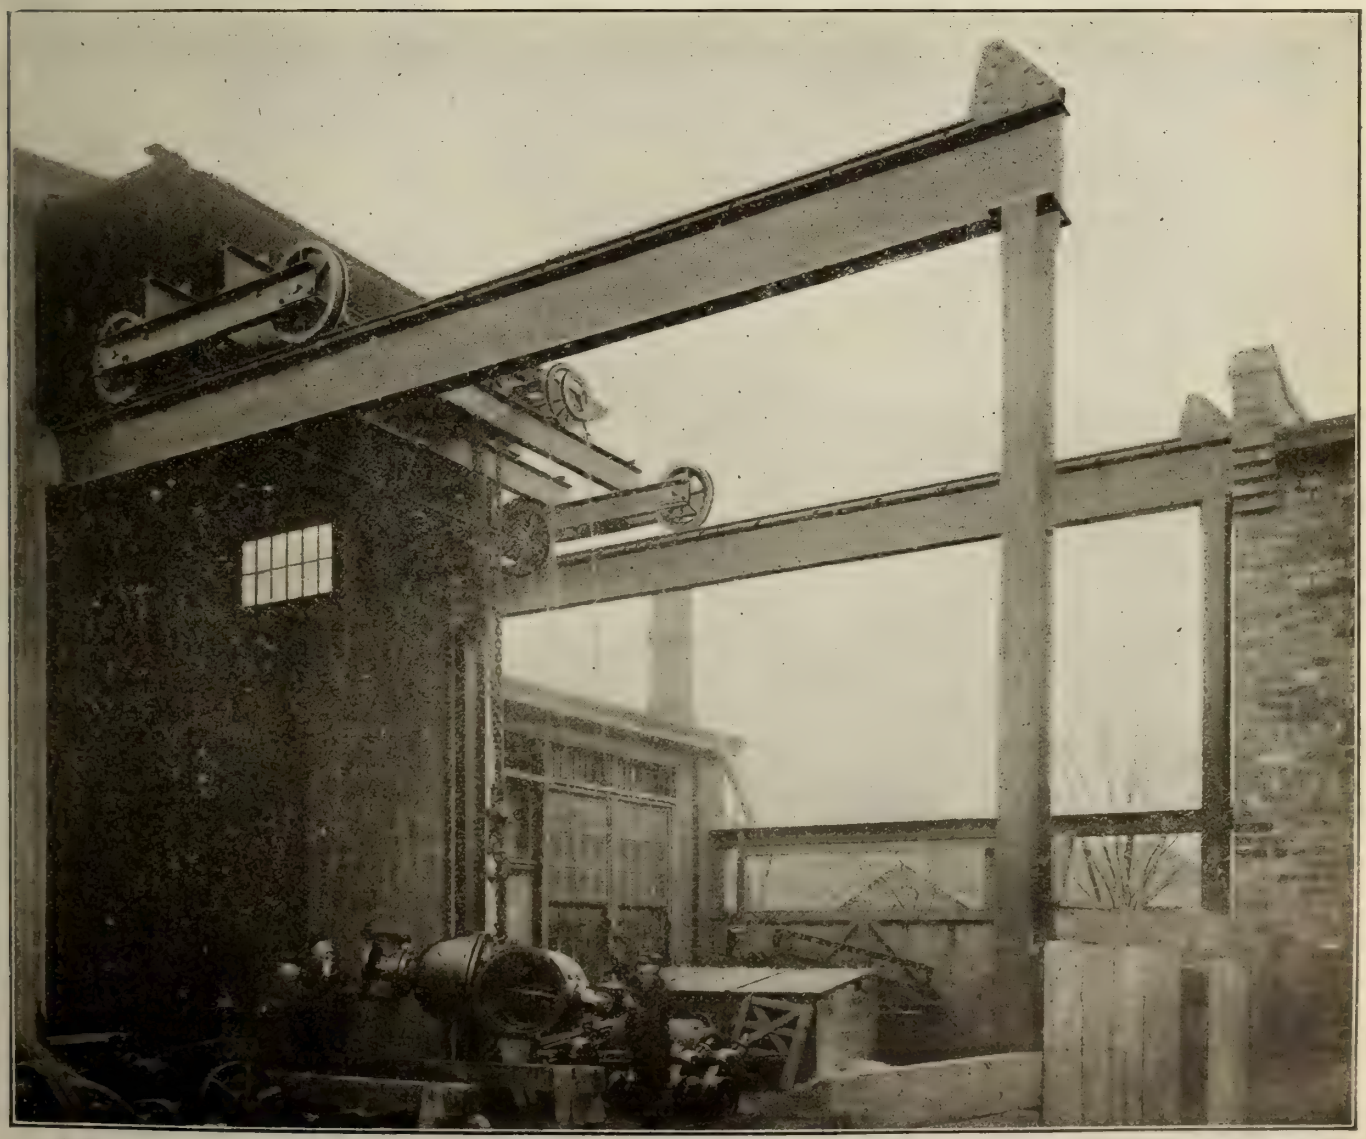
Once you have traced the leak, so to speak, in your methods, the next step is to select from the various items of handling equipment obtainable the particular type that is best adapted to your individual conditions and which will produce the best results at the same time eliminating the greatest amount of time and expense. This ought to be an easy matter, for any concern manufacturing such labor and time savers, are only too pleased, not only to send their descriptive matter upon request, but will even place their staff of expert transportation engineers at your disposal.

At this point, however, it is best to weigh all the various conditions carefully. Suppose, for instance, you find that new equipment of this nature will cost you possibly 30 to 40 per cent. of your estimated savings, and will reduce your handling cost 30 per cent. This looks splendid, but let us go still deeper into the subject.

We will suppose you consider other equipment, which will cost you 60 to 70 per cent. of the estimated savings, but which will save you 100 per cent. handling cost. Which is the better proposition? Of course, the latter installation in this case, which brings the matter up to a definite point, namely that a thorough investigation into the varous details surrounding your own particular problem is absolutely essential.

We know of one case where the actual saving in the handling question amounted to $750,000.00 per year in the plant of one corporation, while in several plants over $100,000.00 was saved every year by tackling this transportation bugbear. The wrong solution in any of these plants would have proved a serious affair, but the matter was attacked seriously and sensibly with the result that the installations were a perfect success.

We hear, in fancy, some one exclaim, "But these cases quoted are exceptionally large concerns." True, but everyone does not turn over such a large quantity of business as these concerns spoken of. This fact, however, does not deter you from saving in like proportion to your annual production, which brings us to the point once more



BY CONSTRUCTING YOUR BUILDING IN THE MANNER SHOWN YOUR CRANE DOES DOUBLE DUTY OF INSIDE AND OUTSIDE WORK. HERE WE SEE AN INSTALLATION OF A HERBERT MORRIS CRANE, 10-TON, TYPE G, MODEL. HERE IS A CASE WHERE FORETHOUGHT COUNTED.

THIS JIB CRANE IS ELECTRICALLY OPERATED AND SUITABLE UP TO LOADS OF 600 LBS. CRANES OF THIS NATURE WERE USED EXTENSIVELY IN ENGLAND DURING WAR TIME FOR SPEEDING UP PRODUCTION. THE CRANE RUNS ON NARROW GAUGE TRACKS OF 3 FT. 6 INCH. CENTRES.

of remarking, "Study your own particular problem, study it carefully, then act accordingly."

There are so many different kinds of movement time savers on the market to-day that to intelligently discuss the problem we had best consider a few of these one at a time.

The Crane

Perhaps the most widely used of all shop equipment is that of the crane, hand, electric and pneumatic. A plant to be up-to-date must have some system of crane installation to convey their work to and fro throughout the shop. In some cases the hand crane is found sufficient, but in other cases, especially where it would be difficult to reach with either an electric or hand crane, the pneumatic hoist, or air hoist as it is generally termed, becomes the favorite. From these observations we gather exactly the same conclusion as before, namely that your own particular condition is the problem to be considered.

To state definitely the actual saving by the use of cranes would indeed be an arduous task, but of one thing we feel sure, that without them, we would be in a sorry state. The saving differs with conditions, depending not only on the location, but the amount of thought which has been spent in their installation. A crane can be rendered practically valueless by poor judgment in installing. When considering such a problem, one cannot do better than first decide on the make and style of crane desired, then take the matter up with the firm manufacturing the product, who will be only too pleased to give the benefit of their former experiences together with suggestions.

There is another form of transportation which is used practically throughout the world, namely that of trucking. This can be either accomplished by hand or power, but in order to follow up our principle of discussing each system separately, let us consider:

The Hand-Operated Truck

These trucks have many uses, so many in fact that it is well nigh impossible to state them all in an article of this nature. Throughout shops of all kinds, in warehouses and at freight terminals you will see hundreds, yes thousands of these trucks in operation. In some cases they are used singly, while in other cases they are hooked up together as trailers, and pulled by means of the electric locomotive, which we will discuss later. But for this section let us quote an example of saving in hand truck handling.

In one plant recently investigated, which used over 30,000 four wheeled trucks, the estimated savings were approximately $750,000 per year, or 100 per cent. yearly returns on their investment.

The first question to decide in consulting a system of four wheeled trucks, to give moveable floor area, is the best designed truck to properly accommodate your product in its various forms. It is a foolish move to attempt to adopt some standard shape of truck if your product takes on different form to any great extent as it proceeds in its manufacture. If you do attempt to follow some standard your trucks will be only partially efficient. Ask yourself these questions:

UNFORTUNATELY SUCH AN IDEAL SYSTEM AS THIS DOES NOT EXIST IN THE AVERAGE MACHINE SHOP. IT IS USUALLY THE HABIT TO GET THE GANG TO HELP YOU LIFT THE WORK ONTO THE LATHE. THIS MORRIS TRIPE-GEAR CHAIN-BLOCK ELIMINATES THE TROUBLE, AND THE AUTOMATIC BRAKE ON SAME KEEPS THE PIECE SUSPENDED AT THE RIGHT HEIGHT TO SUIT THE OPERATOR. HERE IS A SCHEME WELL WORTH COPYING.

THESE FOUR-WHEELED TRUCKS ARE USED IN KNITTED GOODS TRUCKING TO GOOD ADVANTAGE. THIS TYPE OF TRUCK IS HANDLED BY THE EQUIPMENT MFG. CO., CLEVELAND, OHIO.

Should the trucks have ordinary flat platforms?

Should end racks be used?

Should your truck be totally enclosed or should there only be two or three sides to it?

Should the superstructure be solid or slatted?

Should shelves be provided, or should little compartments be made?

From these leads you can readily see the object of the cross-examination with yourself and shop conditions, for by spending a little time in this manner, you will increase to a great extent the efficiency of the truck.

The size of the truck is an important point, for that determines the quantity of product handled at each movement. Watch your clearances, also your heights. Another point which is not often considered is the question of floor surface. One cannot expect a truck or trucks to operate to best advantage if the floor surface on which they operate is not up to proper standard. Decide on the number of trucks you require to quickly handle your product for it is a penny wise and a pound foolish policy to cut down on the number of trucks and decrease their efficiency and cause congestion.

Since ball bearings have come into common use, the trucking problem has been greatly improved, for even with a heavy load on these trucks the design is so arranged that practically no effort is necessary to propel this type of vehicle.

The Electric Truck

The electric storage battery truck is too well known to need any introduction, for practically in every up-to-date plant one can see numbers of these very handy time savers in operation. There are two general types of these trucks for industrial uses. There is first the carrier truck, which takes its load from place to place, then there is the tractor type, which pulls loaded trucks, to whatever department is desired.

The principle of design is practically the same in both cases, electric motor supplied with current from storage batteries doing the driving. Generally the speed of these trucks is so controlled that they cannot travel at more than a predetermined rate. Steering is done by one hand, while the other is on the driving lever. If the driver moves his hand from the driving lever it immediately returns to neutral and the brakes are applied. But as we are not concerned so much in the design of these trucks as we are in their aid in reducing handling cost, let us consider a few examples of cost reducing.

Results That Count

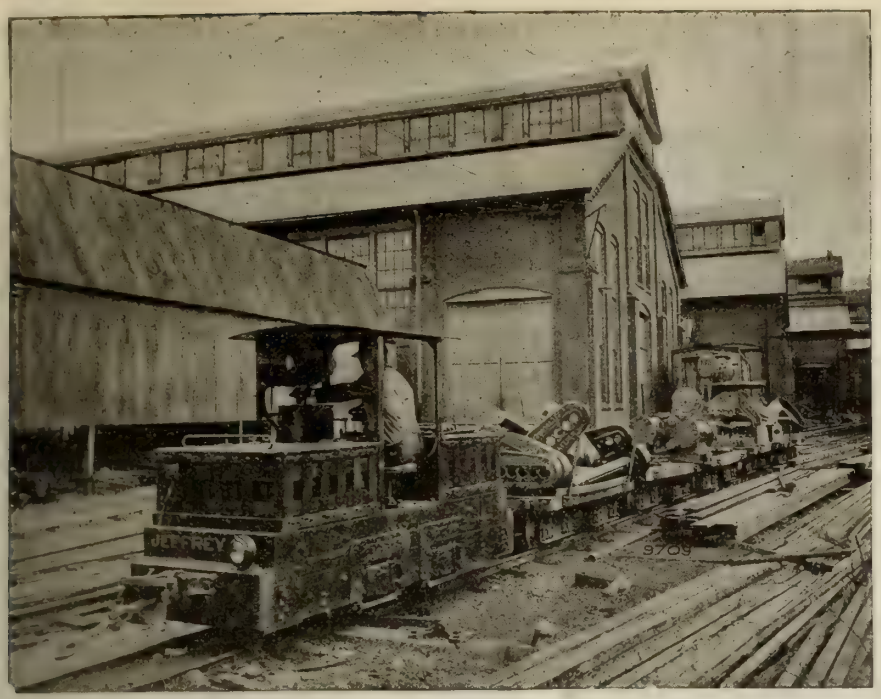
A certain agricultural implement manufacturer installed electric trucks with the following results: Six tractor trucks are now being used to convey raw material from one department to another, where formerly this work was done by 30 men. These new tractors draw an average load ranging from 4,000 to 8,000 pounds over floors of brick, wood blocks and steel plates. Some of the grades

AN ELECTRIC STORAGE BATTERY TRUCK HANDLING MATERIAL IN THE FORGE SHOP. THIS TYPE OF TRUCK IS HANDLED BY THE ELECTRIC STORAGE BATTERY CO. OF PHILADELPHIA.

are as steep as 17 degrees, and range from 25 to 100 feet in length. The speed of these trucks is approximately 4 miles per hour.

In an automobile factory the trucking gang was reduced by 64 men by the installation of eight trucks of various types, varying with the class of work to be done. The average load was not over 1,000 pounds, and the floor areas were good. The finished parts are now handled with less breakage and damage, also there is no congestion

HERE WE SEE A SELF-LOADING ELECTRIC TRUCK MADE BY THE ELWELL-PARKER CO. OF CLEVELAND, OHIO. THIS TRUCK IS OPERATED BY TWO MOTORS, ONE FOR PROPULSION, THE OTHER TO DRIVE THE ELEVATOR. ITS USES AND ADVANTAGES ARE SELF-APPARENT.



A HAULING SYSTEM SUCH AS SHOWN CANNOT HELP BUT REDUCE YOUR COSTS. THIS IS A JEFFERY STORAGE BATTERY LOCOMOTIVE IN USE AT THE OIL WELL SUPPLY CO., OIL CITY, PA. IT TRANSFERS ALL KINDS OF MATERIAL AROUND THEIR PLANT WITH SURPRISING SPEED.

of material as formerly. A saving of considerable amount was also experienced.

In a certain rubber company 16 trucks freed 160 men for other work. This tire company spoken of uses these trucks for handling all hauling in the plant from department to department. The loads run as high as 3,200 pounds, the length of haul varying from 600 to 1,200 feet. High speed is the rule in this plant, the trucks running from 8 to 12 miles per hour. There are no grades, and the floors are wood and concrete. Unnecessary to state a large saving was the result.

Examples such as these could be quoted indefinitely, but enough has been given to prove the point that in every case it pays to move your goods mechanically and systematically. There is no hard and fast rule as to whether a carrier truck or tractor truck is best. This matter rests entirely with your own particular plant and conditions. For short hauls where the routes are short and irregular, and where the driver can easily handle the loads, the carrier truck is the most common. For hauls following regular routes and where there is sufficient work to keep trucks going all the time, with loading and unloading gangs, the tractor seems best adapted to reduce to the greatest extent the trausportation cost.

It is estimated that for a 10-hour day, $1.20 will cover interest, depreciation and upkeep. Of course, this may run higher or lower, depending on conditions.

Much of the operation costs depends on the work being done and the time the truck is actually at work, that is moving material, and the time lost waiting for a load or to be unloaded as the case may be. Without fail watch this latter condition, for here is a great danger point for a leak in the general efficiency.

For heavier work, and run, on the same principle, we have the industrial locomotive. These run on regular small gauge tracks, and the saving which these locomotives accomplish is enormous. Storage batteries, as before, provide the driving power. This, of course, eliminates the fire risk and overcomes the smoke nuisance. Throughout this article are shown various installations of the type of transportation with actual figures of savings.

The Gravity System

There is another transportation system in wide use, namely that of moving material by gravity. It will perhaps be best to quote what one well known firm has to say regarding the system spoken of.

The gravity conveyor is the industrial roller coaster for carrying all kinds of products in every business. It operates for practically nothing, as it uses the free power of gravity, which is on the job 24 hours per day, and 365 days in the year.

To mention what products such gravity systems will convey would be impossible, for boxes, barrels, rolls of paper, brick, tile, lumber, and, in fact all products having at least one flat surface can be carried directly by this means. In the machine shop for instance small parts are placed in tool boxes, while in other plants rolls of cloth, or any products of irregular shape are used, the work is carried on trays, containers or pallets.

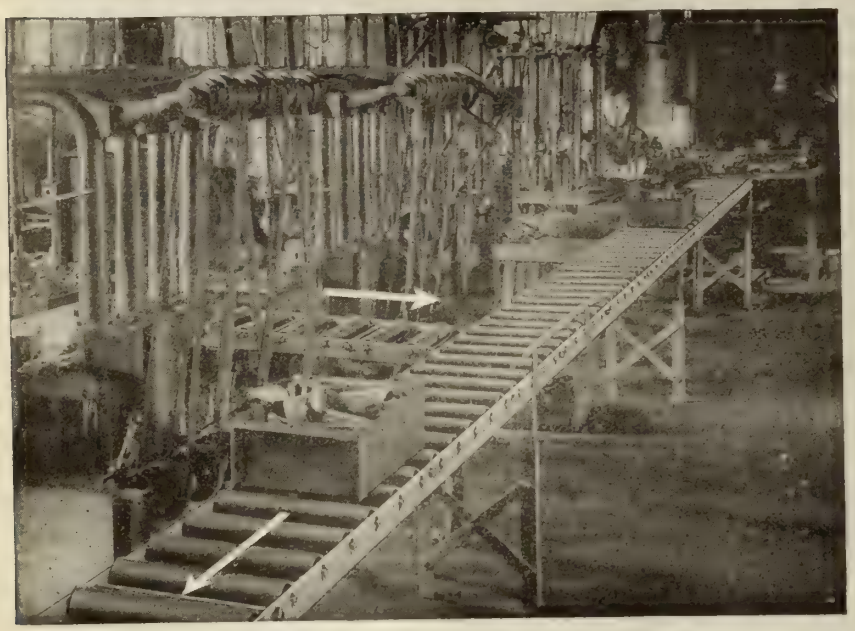
Of course to have an efficient system one must see to it that a system is installed where all rollers run freely on ball bearings. Should economy of space be important the conveyor can be suspended from the ceiling out of the way of machinery and workmen.

Another very strong point in favor of this transportation scheme is the fact that you can use portable sections almost anywhere. This comes in exceedingly handy when unloading cars, or piling cases in storage. These portions can also be provided with hinged sections, which can swing out of the way like a drawbridge when desired.

Curves hold no terrors for the gravity system, for the

THIS IS A CASE WHERE THE ONE MEANS OF TRANSPORTATION HELPS THE OTHER. HERE WE HAVE AN OVERHEAD CRANE WORKING IN CONJUNCTION WITH A JEFFERY INDUSTIAL LOCOMOTIVE. THESE ARE BOTH LABOR-SAVING DEVICES THAT NO LARGE INDUSTRIAL PLANT CAN AFFORD TO BE WITHOUT.

construction of a nice, sweeping curve by the roller system is a very easy matter. A big feature in favor of installing such a method is the small space taken up by the runways. These can easily be run between machines,



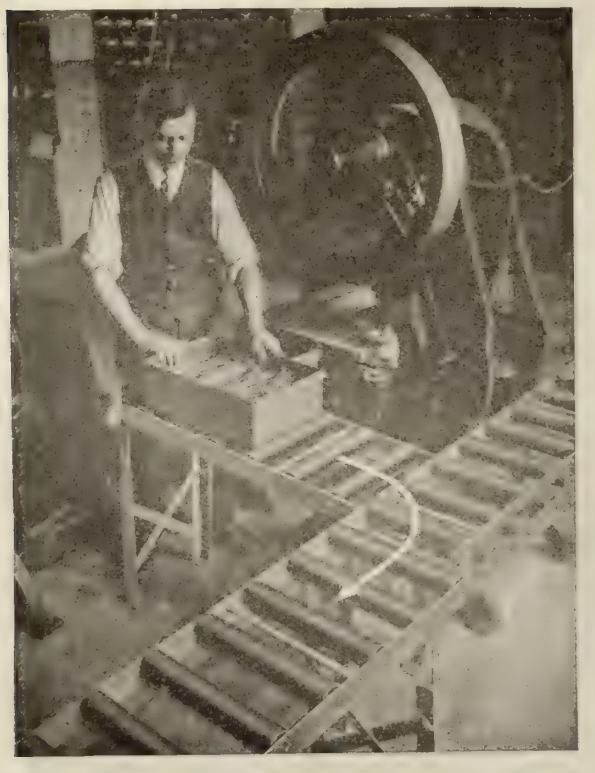
NO ACCUMULATION OF STOCK BETWEEN THESE MACHINES. LAMSON CONVEYORS CARRY TOTE BOXES OF MATERIAL FROM EVERY MACHINE DIRECT TO THE NEXT OPERATION. ONE CANNOT HELP BUT SAVE WITH SUCH A SYSTEM.

THESE CASE-HARDENING BOXES ARE STILL RED HOT BUT BY USE OF THE GRAVITY SYSTEM ARE EASY TO HANDLE. THIS TRACK AS SHOWN CARRIES THEM TO HARDENING TANK, ANOTHER TYPICAL LAMSON INSTALLATION.

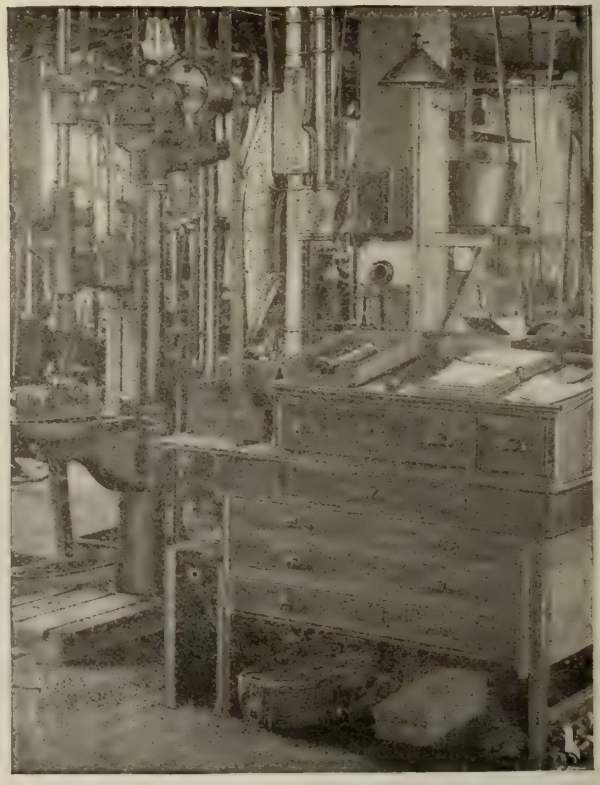
through partitions, around columns and obstructions, in fact they will carry your product wherever you want it.

Lowering devices, spiral chutes, spiral conveyors, boosters and elevators, all come within the scope of this gravity system. Each style has its own particular use and function. A study of the various illustrations throughout this article will really give a better conception to the reader than all the written descriptions are ever likely to do.

The gravity conveyor can be used out of doors to great advantage where rough products are handled. The food product plant, the general merchandise plant, the warehouse, the lumber plant, the department store and factory, the shipping department, the machine shop, the foundry, in fact practically all branches of industry have benefitted



THE OPERATOR OF THIS PRESS MERELY PLACES THE TOTE BOX ON THE CONVEYOR. THE LAMSON CONVEYOR DOES THE REST, AND THE OPERATOR NEVER NEEDS TO LEAVE HIS MACHINE.



THE FOREMAN OF THIS MACHINE SHOP IS IN INSTANT TOUCH WITH THE MAIN OFFICE AND WITH EVERY OTHER DEPARTMENT THROUGH USE OF THESE LAMSON PNEUMATIC TUBES.

by the use of this system. It might well be said that its uses are illimitable, which prompts us once more to remark that it depends entirely on your own particular problem, what system of transportation you install.

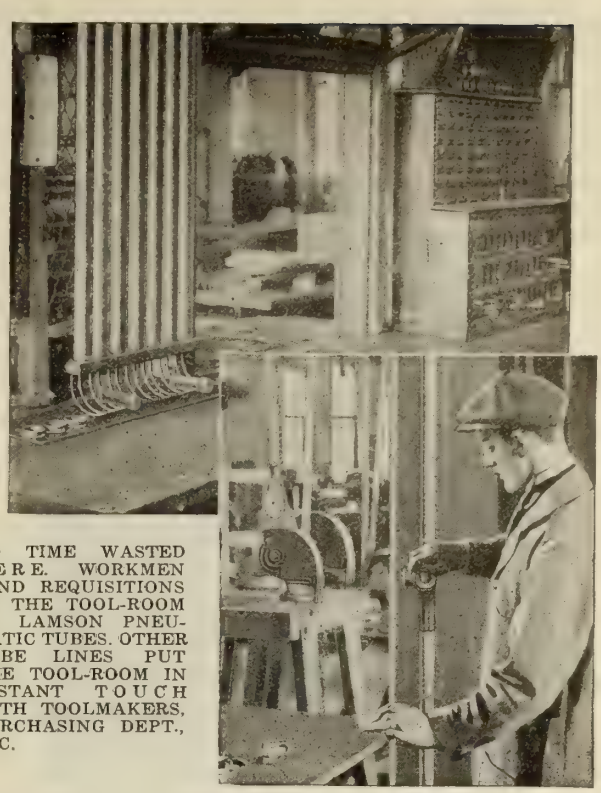
Various Styles, Systems

Then there is the pneumatic tube system of transporting the various papers, orders and materials with great speed from department to department. To go into a detailed description of this method in an article of this nature is impossible, for such a subject is a study in itself. The tube system instantly centralizes all departments. A point not generally known is the fact that these tubes are sometimes as large as 3 in. x 6 in., oval shape, for carrying objects larger than the ordinary letters and general

TOOLS BY THIS METHOD ARE CARRIED WITH LIGHTNING SPEED ABOUT THE MACHINE SHOP OR MANUFACTURING PLANT.

run of work. Tools to the machine shop are easily transported by this method, and the scheme is especially useful if the plant is large, and where a central office issues orders and instructions to the various departments. It practically links up the office and shop in such a manner that at a moment's notice they are in touch with each other if necessary. The use and extent of the tube system depends entirely on your plant conditions, and once more no hard and fast rule can be made in this regard.

Another system of trucking in great vogue is that of the elevating truck. No doubt many people will be surprised when they learn that this type of truck is not



NO TIME WASTED HERE. WORKMEN SEND REQUISITIONS TO THE TOOL-ROOM BY LAMSON PNEUMATIC TUBES. OTHER TUBE LINES PUT THE TOOL-ROOM IN INSTANT TOUCH WITH TOOLMAKERS, PURCHASING DEPT., ETC.

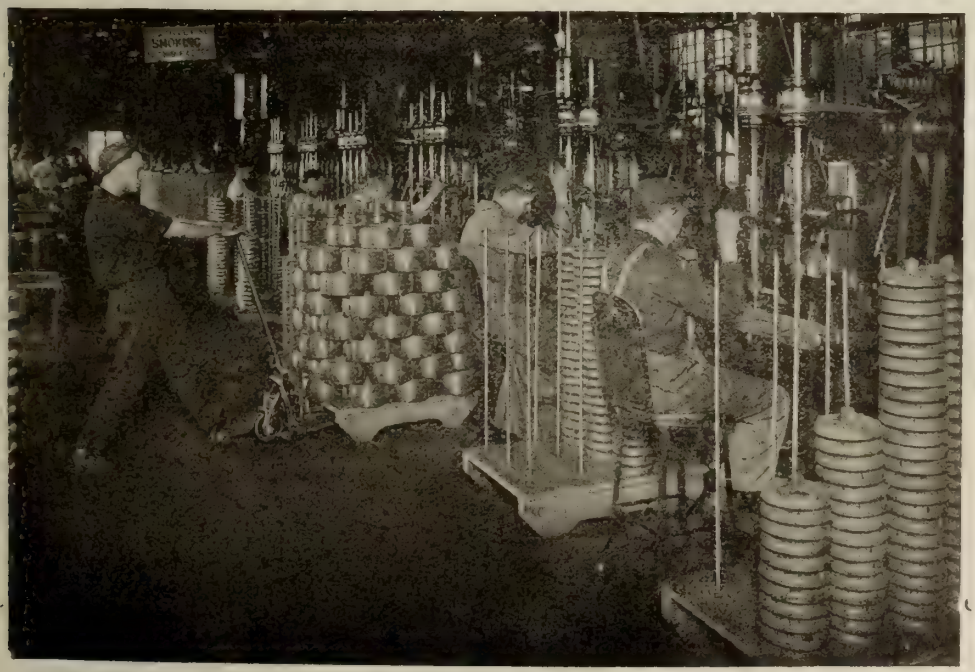
yet ten years old, yet they are widely distributed throughout the world. The first truck of such nature is said to have been built at the paper goods plant of the White & Wyckoff Mfg. Co., Holyoke, Mass., in 1911.

This initial start, meant later the building up of the Cowan Truck Co., Mr. H. W. Cowan being the gentleman who superintended the building of the first truck.

This type of cost-reducer was termed the Cowan Transveyor, and such it is still called. The cost of trucking by this system was reduced to a wonderful extent, in fact a comparison is not amiss but well worth while.

Formerly stock was moved on ordinary trucks which cost from $10 to $25 each, and a sufficient supply for an ordinary factory ran into a large investment. Furthermore, the use of the old style truck necessitated piling stock at start, piling from truck to floor at destination and piling into another truck at destination and piling onto another truck later, when stock was desired in other departments. With the Transveyor system every wooden platform costing $1.50 to $5 becomes a truck the moment the transveyor is pushed under it. There is no piling or rehandling at start or finish.

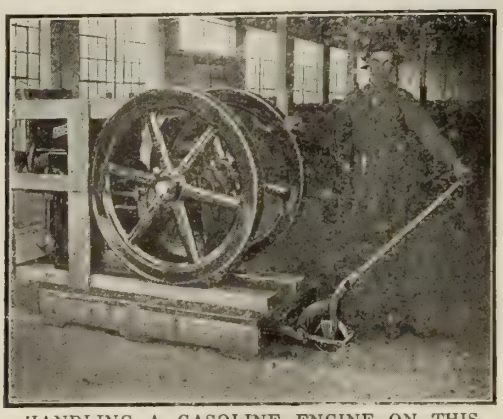
In addition to the economy of handling materials there is, too, a great saving of room as the empty platforms, really trucks, can be tested and piled high in a minimum space when not in use. This is really adding storage space or permitting more space for productive work, something which is not possible with the old style hand trucks.



A SYSTEM SUCH AS SHOWN OF THE COWAN TRANSVEYOR IS CREDITED WITH REDUCING THE TRUCK MEN 25%, STORAGE ROOM 50%, BREAKAGE TO ZERO, AND MAKING IT POSSIBLE TO REPLACE WITH CHEAPER LABOR.

The pleasing feature of the transveyor is that it starts immediately to lighten the labor and to reduce the cost of moving materials. In some factories the results secured in a single month repay the outlay on transveyors and platforms. After a short time other improvements are noticed such as a speeding up of the work in all departments, the promotion of system and cleanliness in the plant and the decrease of danger to stock by bursting water pipes, as the stock is removed from ordinary risk when piled on platforms instead of on the floor.

Although designed for use in paper plants the transveyor is widely used in plants of various kinds all over the world but especially so in the United States and Canada. Large fleets of elevating trucks may be seen hard at work in the largest industrial plants in these



HANDLING A GASOLINE ENGINE ON THIS TYPE OF TRUCK WITH PERFECT EASE.

countries and then again hundreds of small plants, especially machine shops are using a single transveyor daily. The device is used for practically the same purposes in all these places, namely to reduce the cost of moving material and to promote system.

To illustrate results which have been attained by the use of the elevating transveyor we quote the actual figures.

Mr. C. E. Stone, purchasing agent of the Chain Belt Co., says, "Seven men and ten ordinary trucks was our former need. Now five with the transvevyor system handles the work easily and saves us $1,050 yearly in labor cost alone.

YOU CANNOT HELP BUT NOTICE THE SAVING OF SPACE IN A SYSTEM SUCH AS ILLUSTRATED. NOTE THE ORDERLY APPEARANCE OF THE STORED WORK.

Terrance Scullin, master mechanic, Harvard shops of Cleveland Railway Co., comments as follows, "When we moved into new shops we needed equipment to facilitate quick handling of material in bulk to the various operations. Transveyors, because of their durability and ease of handling, made us quick to realize their value for our purpose."

Charles Kantenwein, foreman of the machine shop, The Winton Co., Cleveland, says, "Six Cowan Transveyors are now saving us $5,280 a year."

J. I. McCormick, engineer of methods of Republic Motor Truck Co., Inc., Alma, Mich., says, "The two transveyors and 200 skids cost less than half as much as trucks formerly used, and they reduced our trucking gang by 6 men, saving $5,400 a year, or over $16,000 to date."

These figures speak for themselves, and we leave the various illustrations of this system to speak with these figures.

It is hard to find any article used in industrial plants that became a success as quickly as the elevating truck and it will be just as difficult to find a plant that cannot make profitable use of the transveyor. Another point in its favor is that this style trucks are built in practically every style to take care of various conditions.

Another system of transportation is the tricycle method. This scheme is particularly adapted to the delivery of parcels too heavy for the pneumatic tube system yet too light for the trucking system. These tricycles are narrower and lighter than a truck, and are especially suitable for use in crowded aisles. The small cost is a big feature, and for mail delivery especially it is estimated that one tricycle carries eight times as much as one boy and makes the trip in less than half the time. In one plant alone these vehicles travelled a total of 14,295 miles.

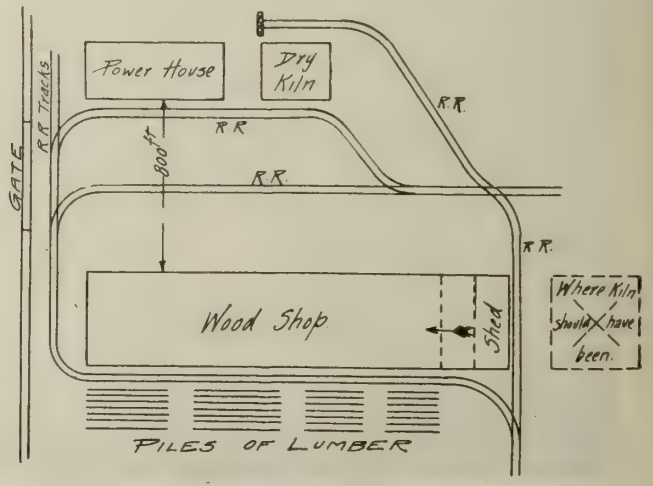
Girls in uniform often run these tricycles to good advantage, as they are light and easy to pedal. We show in the heading of this article an installation of such nature. Here again we realize that as a well known writer once said, "There is more than one way of skinning a cat. In other words the way to get over transportation problem depends on your conditions. Even after you have studied your conditions you will find yourself sometimes in a dilemma when you discover there is more than one way you could get around your trouble.

Caution, above everything else, is essential, for a step in the wrong direction means a loss of real money and time, not to speak of a user who would remark, "Transportation may be all right for others but not for me," while a step in the right direction means a saving in time and money, and an enthusiastic booster for transportataion methods.

The Danger Point

To illustrate the danger of choosing the wrong solution to your handling problem, the writer quotes two cases which came to his attention not so very long ago. The first case was as follows:

In a certain agricultural implement plant one of the products handled was that of long iron beams. To facilitate handling specially constructed trucks were made, but the fact was lost sight of that the problem of getting



PLAN VIEW OF THE ARRANGEMENT OF BUILDINGS.

these trucks into the elevator still remained. It was necessary to trannsport these beams up four stairs.

Too late they realized that while these trucks helped in certain ways, still the problem was not solved. Later it was solved in a very easy manner. An outside elevator, of double chain design, was made outside the building. At certain portions of the chain long hooks, or rests projected. Into these, lengthwise, were placed the beams. Upon reaching the proper height they went through a slot in the wall built specially to accommodate this work. The method proved highly satisfactory and saved this firm considerable money, not to speak of speeding up the work.

The next example, unfortunately, has not reached the stage of successful solution. To explain the blunder fully the writer has prepared a little sketch which is shown with this article to fully illustrate his point of view. Referring to this sketch readers can readily grasp the general lay-out of the buildings with which we are concerned.

In order to save steam pipes, this firm built their dry kiln near the power house, but in so doing proved the penny wise pound foolish theory. True, they saved in the amount of piping used, but since they have realized what an error they have made. Had they built the kiln at the portion marked with a cross on the sketch they would have saved themselves this extra handling trouble.

The kiln, however, went up near the power house, with the result that yearly this firm is losing considerable money, owing to the fact that the lumber must go through the following stages of transportation:

On entering the sidings on the cars it is first taken from the cars and hauled to the piling yard. Later it is taken from here to the dry kiln, a distance of over 1,000 feet, after which it is brought back over practically the same ground to the distributing shed. It is now passed into the wood shop itself, but not before all this wasted time, labor and expense has been spent on it. It will cost considerable money to construct a new building for kiln purposes, although, as this firm candidly admits, that is likely what it means in the end anyway.

From this illustration we cannot help but see that not only does the system of transportation enter into the solution, but also the routine of operations throughout the plant. It is sometimes good policy to change the system of routing to meet with the transportation system, should the corresponding result be worth while.

Which is the Most Profitable?

In an article such as this, dealing only with some various systems in use, we cannot attempt to advise which is most profitable. That problem is strictly up to you. What we will say, however, is this, that if you have no record of what your product is costing you to handle, ascertain this without delay, for it is a more serious matter than many imagine.

Having once discovered this point, then consider what it will cost you, should you adopt some method of transportation. Gather together data from the various firms throughout the country. You will find them eager to help you and the advice of their engineers is worth money to you. Having got this far, weigh the matter carefully, then decide on the scheme best suited to your requirements. Install this system, giving clear thought and judgment as to how it had best be installed to make it really efficient. After you have done this then you can sit back and feel sure that you are going to watch a transportation system in operation which is going to lower your handling costs and place more money for you in the treasury.

Throughout this article we have illustrated various installations together with data showing that mechanical means of transporting goods and material really brings results worth while.

We are indebted to the firms whose names are mentioned underneath the illustrations for the use of these photographs, and feel sure readers will benefit by a study of these illustrations.

VIEW IN A MUNITION SHOP, WHERE THIS TYPE OF TRUCK WAS USED TO SPLENDID ADVANTAGE.

Growth of The Geo. F. Foss Mach. & Supply Co.

Close of the War Brought a Situation That Led Them to Equip Plant For the Rebuilding of Used Machinery—Large Business Grows From Small Beginning

THE steady expansion of the Geo. F. Foss Machinery and Supply Co., Limited, of Montreal, has been an outstanding feature of the past eight years in machine-tool activities. Circumstances have proven a great ally in bringing the business up to its present high standard of service and efficiency, but it is mainly due to the ability and integrity of Geo. F. Foss and his able associates, that this firm now ranks as an equal to many of those of longer standing.

It was in the year 1911 when Geo. F. Foss, then a traveling salesman, decided to branch out on his own account, and, with Mr. M. A. Fuller, established the firm of Foss and Fuller, occupying a small office on St. James St., in the leading machine-tool district of Montreal. Success followed closely on the initial efforts of the new firm and at the termination of the first year's business, the interests of the junior member, Mr. M. A. Fuller, were purchased by Mr. H. W. Hill. Continued success followed the partnership of Foss and Hill, and in November, 1917, the interests of Mr. Hill were taken over by Geo. F. Foss, and the latter formed the incorporated company of the Geo. F. Foss Machinery and Supply Co., Limited.

For many months prior to the formation of the present company—during 1916 and 1917—the country's demands for machinery to take care of the munition requirements of the Empire, necessitated the concentrated efforts of every machinery house in Canada, in co-operation of manufacturers, for the scheduled production of shells and other war supplies. That the firm of George F. Foss Machinery and Supply Co. was among the leading houses in this respect was exemplified in the remarkable growth of the past two years. At the time the present company was incorporated they were housed on the ground floor of the four-storey building at 305 St. James St. The phenomenal development of the business, during the year 1917, meant that additional office and show-room space would have to be acquired for the steadily increasing business. Incidental to the formation of the present firm, therefore, the second, third and fourth floors of the building were taken over, and this extension provided further opportunity to entrench themselves into the goodwill of their customers, who had faithfully supported the sincere efforts in their behalf.

Another Development

The termination of the war and the cessation of all activity in connection with the manufacture of munitions created a situation unprecedented in the history of the machine-tool industry, where the country was virtually flooded with machinery of every description, and ranging from brand new tools to old and used equipment. The solution of the two extremes was a comparatively easy matter, as the first was taken care of in the usual way, while the latter was immediately relegated to the scrap heap, or sent to the cupola. The vital problem was the disposal of the tools that had seen varying periods of service in shell making and had destroyed their efficiency for ordinary domestic work. The volume of standard machine tools in this category was of considerable proportion, and something had to be done to reclaim such tools, and make them fit for useful service. To this end the Geo. F. Foss Machinery and Supply Co., Limited, have purchased a large building on Brennan

GEO. F. FOSS.

HEAD OFFICE AND WAREHOUSE OF THE GEO. F. FOSS MACHINERY & SUPPLY CO.

REBUILT MACHINERY WAREHOUSE OF THE SAME FIRM.

St., formerly owned by the Canada Metal Co., and after making extensive improvements to the property established a warehouse and machine shop and will devote it to the rebuilding of second-hand machine tools and other used equipment. The purpose of this new department is to overhaul such tools and make them as accurate as any new machine.

The firm now have ten traveling salesmen constantly on the road, covering the whole of Canada. They also have a branch established at Sault Ste. Marie under the supervision of R. H. Wood as general sales manager for Western Canada. The personnel of the firm is Geo. F. Foss, president; Chas. W. A. Moore, vice-president; W. A. Downing, advertising and small tool manager; A. G. Clarke, secretary-treasurer.

The Personnel of the Firm

George Foote Foss is a Canadian by birth, being born in Sherbrooke, Que., in the year 1876. His early education and mechanical training was obtained through various scopes along the mechanical lines of machinery and electrical equipment. His business career started in the year 1911, entering into partnership with Mr. Fuller, and later forming the present company of the Geo. F. Foss Machinery & Supply Co., Limited, of which he is now president.

Chas. W. A. Moore, the manager of the machine tool department, is a Canadian, born in Toronto in 1880, but when yet a lad removed with his parents to the Town of Lachute, Que., where he obtained his early education. At the age of sixteen he came to Montreal, where he served in several of the more important machine shops for different periods. In 1906 he accepted the position of fore-

man with the Allis-Chalmers-Bulloch Co., and after three years with this firm was appointed to the position of superintendent of the International Steel Co. of Montreal. He served in a similar capacity with the Buffalo Forge Co. and also with the Hall Engineering Co. of Montreal. In 1915 he became associated with the firm of Foss & Hill, and has been connected with this firm throughout its recent re-organization under the name of the Geo. F. Foss Machinery and Supply Company.

W. A. Downing, advertising and small tool department manager, is a native American, born in Waltham, Mass., 1888. His boyhood was spent in Waltham and Boston, and his engineering experience was obtained through many of the leading machinery manufacturers throughout the United States. He has specialized on small tool equipment, serving with many of the leading manufacturers. He became associated with the Geo F. Foss Machinery & Supply Company Limited, about three years ago and was placed in charge of the small tool department, being later appointed as advertising manager.

A. G. Clarke, accountant with the Geo F. Foss Machinery and Supply Company has had this position for the past five years. Prior to his present connection he was three years with the Amalgamated Asbestos Company, and three years with the Canadian Car Company, in a similar capacity.

Several times during the same season heavy floods lifted a large wooden pipe line, supplying a hydro-electric power station clear of its supports and battered it against its ballast bed. Yet examination at the end of the season showed that the pipe was perfectly sound and had retained its circular shape throughout. This is noteworthy, as the pipe was almost four feet in bore, was strengthened only by loops, and was anchored only at the intake. It seems to indicate, too, that wood-stave pipe is a great deal stronger than is generally supposed, and is well fitted for use in hydro-electric plants.

A new device for softening the seals of storage batteries by steam works automatically. A steam generator, a steaming box and a water supply tank are its essential parts. The generator consists of a small cylindrical tank placed over a little gas, oil, or gasoline stove. It contains a small float which operates a plunger to close the water in-take valve as soon as the water reaches a point about three inches from the bottom. In this manner the amount of water in the tank is automatically controlled to remain constant so long as the outside tank is replenished and the mechanic can put a battery in the steam box and leave it without attention while the seals are being softened, while he does other work.

WELDING AND CUTTING

Interesting Examples of Welding and Cutting

Discussing the Oxy-Acetylene and Oxy-Hydrogen Methods, Together With Detailed Data, Covering the Examples Illustrated —The American and French Torches Are Described

By FRANK C. PERKINS

THE accompanying illustration, shows the cutting of a 36 in. shaft by means of an American cutting torch, developed at Boston, Mass., the details of construction being indicated in drawing, Fig. 2. The welding and cutting torches, noted in Figures 3 to 9, indicate the methods of oxy-acetylene welding with torches, developed at Bordeau, France, by Maurice Ledoux & Co.

This American cutting equipment is extensively used in steel foundries for cutting off risers from 6 in. to 26 in.; in larger forge shops to cut billets, shafts or squares out of crank shafts; in junk yards to cut up heavy stock. It is used on all warships liable to get into action for the quick removing of debris. A small investment of a few hundred dollars will save millions of dollars invested in a ship and many lives besides.

The pictures of the 36 inch cut show plainly how this torch just walks through these heavy thicknesses. These have been very successful hand cuts made on 26 in. solid and 36 in. hollow shafts. In short, the equipment has proven to be reliable and easy to run. Interesting speed tests made by operators of the Watertown Arsenal on 15 in. risers show cuts made in 9 and even 8½ minutes, the cuts being as clean as if cut by a saw—an excellent performance, as will be admitted.

The Boston Bulldog cutting equipment is a heavy duty equipment, therefore every part of it is specially constructed for this work. The regulator is one of exceptional dimensions. It carries a safety release built on the principle of a regulator, set to blow off at 250 lbs. pressure and is attached to a manifold so as to connect 4 oxygen cylinders with this one regulator. This produces an even flow of oxygen. As a combustible gas, hydrogen is preferable, as its chemical action is steadily keeping the slot clean which increases the cutting action of the oxygen. Oxy-hydrogen has a peculiar action on the tip holes, clogging their outlets up after a while, and for good working conditions, the hole outlets have to be reamed out once in a while in order to preserve their original width. Otherwise there is nothing to interfere with the perfect working.

The American welding torch is carefully designed, so that the mixing chamber mixes the oxygen coming through

CUTTING 36-INCH SHAFT WITH CUTTING TORCH DEVELOPED AT BOSTON, MASS., BY THE GENERAL WELDING AND EQUIPMENT CO.

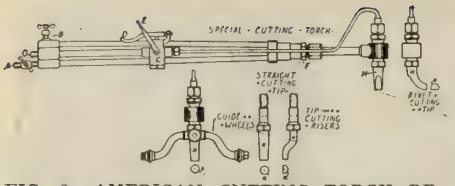

FIG. 2.—AMERICAN CUTTING TORCH DEVELOPED AT BOSTON, MASS.

the centre hole into which the acetylene is sprayed in through a number of fine side holes, thus producing a perfect mixture. The handle is screwed onto the torch base and can easily be removed by loosening a set screw. Four large vent holes are drilled through the base and the mixing chamber castings, so as to procure a perfect ventilation. The thread for acetylene is ¼ in. pipe and for the oxygen inlet ⅜ in. pipe, so that the hose cannot be connected wrong. The mixing chamber is far removed from the tip end or heat zone. The unmixed acetylene can therefore not get overheated and cause flash-backs through decomposing, nor can it get so hot as to carry in expansion and cause fluxions of the mixture, thus changing the character of the flame. The flame, once set neutral, will stay neutral, regardless of the varying heat at the tip end.

If it is desired to see the difference between a torch mixing in the head and one as shown, mixing far away from it, it is only necessary to try both on a deep, heavy break, where all the heat comes back on the torch end. The former will soon start flashing every few minutes, and the latter will operate without interruption. Naturally, the weld can then be made in less than half the time and with less than half the amount of gases. The flame will keep absolutely neutral and the weld will be strong and uniform. Rubbing the lighted tip against flat faces and showing that the tip will not flash, never proves how a torch will work under really trying conditions.

It is claimed to be a combination welding torch, that is, a torch base with two extensions is used, so as to have either a 16-inch long torch or a 22-inch long one. In special cases, a still longer extension can be supplied to make the torch 30 inches over all. Thus the operator can just connect that extension which is the most suitable for his work. There is no need of having several torches of different lengths. One torch base with the two or three extensions would practically give you two or three torches in one. Every length of torch is well-balanced, as the principal weight is in the handle and the torch end is so non-obstructive that even difficult spots can easily be reached. Each torch is supplied with a set of nine tips, able to do all possible work. Every tip can be regulated within wide limits from full heat down to ¼ heat without ceasing to work properly.

Aside from the gas consumption of the preheating flames, which is only a small percentage of the total consumption, the main expense is the oxygen used for the cutting and in order to get a real idea for this expense, it is necessary to start from the theoretically necessary amount of oxygen to burn the iron or steel out of a slot of a certain size, and to figure out how many cubic inches have to be burnt out. You then find that burning out a slot of ⅛ inch width in a 1 inch plate over the length of 1 foot, we have to use a minimum of 1.9 cubic feet of oxygen. For 2 inch plate it would be double and for other sizes in proportion. A 1-16 inch to 3-32 inch slot would be about the regular width when cutting thickness of 1 inch and over by hand.

For smaller stock and when cutting with a machine, this slot could be reduced less than 1-16 inch and therefore the theoretical consumptions cut down in proportion. All these finer cuts have to be made with specially fine type, which need special care to keep them in shape and must be operated by a first-class man. They show what can be done under special conditions, but would not prove a success when made by the average class of men.

This theoretical consumption is, of course, far below the amount you really consume, because it refers to pure oxygen and pure iron. Now, the commercial iron and steel contain carbon and sometimes special ingredients, as nickel, manganese, vanadium, etc. If the carbon goes to such a percentage as in cast iron the oxygen will not cut any more and from this you may see how the consumption of oxygen increases with the percentage of the ingredients. Furthermore, commercial oxygen is not absolutely pure, 99 per cent. being a good average for the electrolytic oxygen and 97 per cent. the average high mark for oxygen made from air. Practical tests with cutting show, however, that the oxygen consumption increases 25 per cent. if you cut with 97 per cent. pure oxygen against a 99 per cent. pure one.

Then there is some surplus of oxygen

FIG. 4.—FRENCH TORCHES OF MAURICE LEDOUX & CO., OF BORDEAUX.

FIG. 3.—OXY-ACETYLENE WELDING BY MAURICE LEDOUX & CO., BORDEAUX, FRANCE.

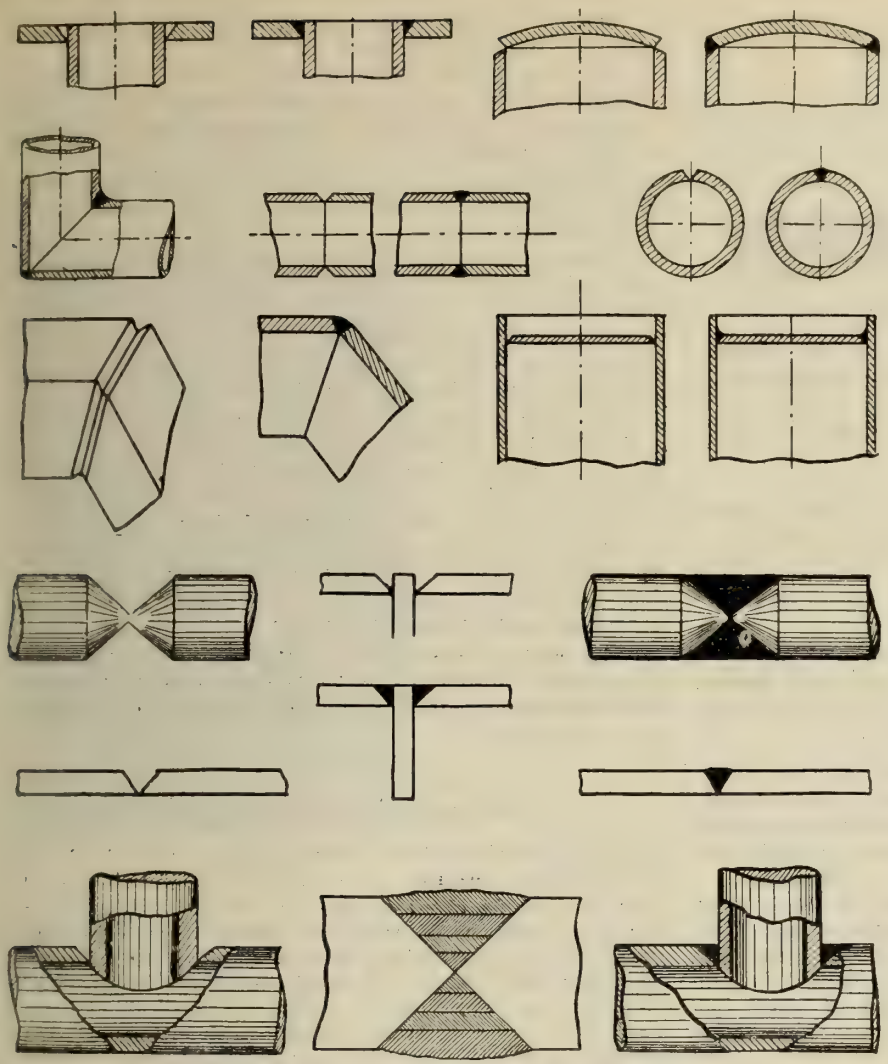

FIG. 5.—EXAMPLES OF FRENCH WELDING METHODS.

necessary to blow the burnt iron out of the slot. Then there is the human element. Some operators cut slower than others, or have an unsteady hand, which means a wider and longer cut. Others move the cutter too quickly and do not cut all the way through and have to cut parts over again. Others use pressures far in excess of what is needed and simply waste oxygen. Then a great deal depends on the kind of an oxygen reducing valve you are using. Only the best kind of valves feeding without vibrations, such as our double diaphragm valves with forcibly guided seats, are good and economical for cutting. Finally there is a great difference in consumption if the iron or steel is rusty or full of scale, or if you have to cut through several plates bolted or riveted together.

It is stated that the bulk of cutting is done with oxygen and acetylene as a preheating flame, and for thicknesses up to 1 in. and even 3 in. to 5 in. it might be handier; but when it comes to heavy cutting, from 5 in. and up, and hydrogen can be supplied at a reasonable price, hydrogen is preferable. Whenever it comes to heavy cutting, 8 in. and more, hydrogen should be used exclusively, if easily procurable. The oxy-hydrogen flame is not so easily adjustable as the oxy-acetylene flame, as the cone is difficult to see. Therefore, it is a little hard for the beginner to adjust the preheating flame right. In some instances hydrogen could be mixed with a small percent. of oil gas and then the cone comes out bright.

Another gas for cutting is the so-called "Drigas," a light oil-gas which does not liquefy when compressed into cylinders. It is good up to 8 in. cutting. In the natural gas district, natural gas can be used to advantage. Heavy thicknesses averaging between 2 in. and 5 in. can be cut with any of the mentioned gases, and it is more a calculation if these other gases can be as easily procured as acetylene, and if the price of the gases is favorable. If the price of acetylene is 2 cents per cubic foot, the other gases must not be higher than 1¼ cents per cubic foot, in order to compete commercially. For every heavy cutting, however, hydrogen is the only gas to use to advantage. For cutting in narrow places, as inside of boilers, many prefer compressed oil-gas, regardless of the thickness to be cut, as this gas has the lowest explosive range of any of the gases mentioned. Should a hose be damaged in these tight places and catch fire, it is better for the operator to face a lazy burning and very little explosive gas than acetylene or hydrogen.

Expensive brass and bronze brushings are often thrown out of production and consigned to the scrap pile at inspection benches on account of being turned undersize. These may be saved by building up the diameter with copper plating, the expense of so doing usually being slight in comparison with the value of the article.

The old Greek custom of hurling into space their spears, arrows, etc., by means of the catapult, is proving mighty handy in these modern days, for we now launch our airplanes by this same scheme. The catapult runs on a two-rail platform, and is operated by compressed air. The installation is used on board ships, and has proved a decided success.

When silver-plating steel or brass articles, much annoyance is caused by the scaling off of the silver during the burnishing process. This may be very easily avoided by immersing the article for a few minutes in a hot solution of potash or soda, and rinsing it without handling in water. It should then be dipped in dilute nitric acid, removed and scoured with a stiff brush or fine sand if necessary. Attach the wire, dip it again momentarily in the acid, pass it rapidly through clean water and immediately place it in the circuit in the bath.

Many mechanics have had their patience sorely tried when pouring lead around a wet or damp joint, to have it explode, or scatter from the steam generated by the heat of the lead. This blowing may be avoided by putting a small piece of resin into the ladle and permitting it to melt before pouring the lead.

Let Us Get To Work

"WE had considered closing down until next season, but we have decided to go ahead just as soon as we can get the men back in the shop."

That is one of the finest speeches it has been our good fortune to hear for some time past. The firm in question had stated, not ten days ago, that the selling season was passing and they would have no particular call for their output now as it would be too late.

The closing of that shop for the rest of the season would have meant that hundreds of people would have to look elsewhere for employment. It would mean that a Canadian product would not be as definitely and as largely on the market next season. It would mean that a large and efficient organization would have been more or less disrupted.

But the place is going to work. Chances are that this morning the doors are open and things are getting under way.

In other words they are going to work.

We are suffering from lack of production.

Less production per capita is not going to help wear down the 4½ per cent. exchange rate that is smothering Canadian money in New York.

Less production per capita is not going to make conditions in the shop any better for the men who work there.

Less production means less to sell, less to put into the pay roll, less to expand with, less to build decent factories with, and less to go out and find new markets.

For almost five years we have been working at destruction. For six months thousands have held back owing to strikes. We are where we are in spite of conditions, rather than by their assistance.

Now, then, let us get to work. Tinkering with conditions can easily be carried to such lengths that the tinkers on both sides will find they are not able to step up and put the peg in when they wish to call a halt.

Creating New Conditions

THE striking machinists in Toronto and some of the other centres have returned to work. The strike was neither a total failure nor by any means anything approaching a success.

The best thing for both sides is to forget it and work as hard at building up conditions that will make strikes impossible, as they have in bringing about and fighting strikes.

There are new conditions coming into industrial life. Only the self-blinded cannot see them.

The manufacturer who is going to win is not going to run his shop on the card-index system.

A man has got to be something more than a number on the time clock.

If efficiency systems would bring about the best feelings between shop and office this would have been brought to pass long ago.

You say there are too many men in your shop to know them all. Perhaps, but that is no reason for not making the effort.

Do you enjoy the confidence of your men? Did you ever stop to inquire how they were getting along? Ever take an interest in anything that concerns them?

We know manufacturers who are having the best possible time by thinking about the men who are working in their shops. They go out of their way to become acquainted with their pay roll. Do they lose anything on this account? Just ask some of them.

They are getting something more than a day's work. They are nipping strike talk in the bud. They are building up an atmosphere where a strike would be regarded as injury in the house of a friend.

The employer can take the initial step in this direction. We believe in many cases he is willing to do it. The men will respond. Do not take it for granted that they will not.

Buried Treasure Again

THE uncovering of lost treasure from the bed of the ocean has exerted a fascination over the minds of men from early times. From day to day new schemes for salvaging sunken vessels are sprung on an expectant world, to dazzle susceptible minds for a few brief moments and then fade away from sight and memory. Most of these schemes would be perfectly practicable if it were not for certain fixed and immutable laws of nature. One of the most important of these is that every 2.3 feet depth of water exerts a pressure of 1 lb. per square inch on the surface of any object immersed in it, the effect of this pressure being to set very definite limits at which diving operations can be conducted.

One of the latest of these schemes has been evolved by the United States Ship Salvage Participating Syndicate. They have borrowed the famous tank from the battlefield, and are going to ask it to become an amphibious animal, and conduct constructive work on the bottom of the sea, instead of destructive work on the surface of the land. The tank can be built with strength to withstand the pressure of the sea at whatever depth it is necessary to operate. It will be directed from above electrically, and in order that the operators can see just what it is up to, an instrument called a "subsea visionscope" has been invented. The idea is that the tank will be lowered to the bottom of the sea, carrying wire cables, the ends of which are brought up to the surface on each side of the sunken vessel. All being ready, the operator on the surface applies the current, at the same time keeping a watchful eye directed down the subsea visionscope. The tank immediately gets busy burrowing under the wreck thus passing the cables under her bottom. Air containers are attached to the ends of the cable and inflated, upon which the buoyancy of these air vessels raises the vessel from the bottom.

Could anything be simpler?

Here is a chance for those who are getting bored with the tameness of the mining market to get a little quick action. The syndicate is going to be capitalized at $5,000,000, in $1 shares, so there is really no reason why everyone should not get in.

Now that one cannot put a little bet on an "also ran," the romantic interest of these salvage operations should have an appeal all its own.

Has Designed Many Cars

FEW automobile engineers can equal the record of J. G. Perrin, who has recently been appointed assistant general manager and chief engineer in charge of production of Willys-Overland, Limited, Toronto.

Like a good many men who have made their mark in America's third greatest industry, Mr. Perrin began his career in the bicycle business. He started with the H. A. Lozier Company, bicycle manufacturers, Toledo, Ohio, as a draughtsman. Later he went into the machine shop, and after serving there for a number of years, through various departments, he returned again to the engineering department. Shortly afterwards he became chief engineer of the company. In 1897 the Lozier steam carriage made its appearance and was the first of many famous cars to be designed by J. G. Perrin. The first fore-door car built in America, and the first streamline car were Perrin productions. Lozier cars of Perrin design figured prominently on the speed ovals of the world, and have captured "first money" time and again. Among the notable Lozier winnings was the Vanderbilt cup in 1911. Following this, Mr. Perrin was appointed vice-president and chief engineer over the combined works of the Lozier Motor Car Company of Detroit, Mich., and Plattsburg, N.Y.

J. G. PERRIN.

After twenty years' service with the Lozier Company, Mr. Perrin became chief engineer of the Timken Detroit Axle Company, where he remained until the war, when he was called to Washington as a member of the Aircraft Production Department. Through this work he came into touch with aircraft division of Willys-Overland, Limited. At the instance of that Company, and with the consent of the U.S. Government, Mr. Perrin assumed charge of the aircraft division of Willys-Overland, Limited, at Toronto. Before the close of the war his company were producing five complete eight-cylinder Sunbeam Arab airplane engines in an eight-hour working day. In this work Mr. Perrin achieved the distinction of winning the commendation of the Air Board, which was prompted by the high quality of the workmanship exhibited in these Canadian-built, British-designed airplane engines.

He is now devoting most of his time to the perfecting and production of the new "Overland 4" car, a light automobile that is expected to embody improvements of a rather revolutionary character.

A small electric water heater, only 12 in. high, is now manufactured for attachment to faucet, directly or with a rubber tube. The water then flows through porcelain tubes in which non-corrosive resistance coils heat it progressively to the required temperature. The faucet from which the heated water is finally drawn is so associated with the electric snap switch that the current is not turned on until the hot water is actually wanted. If cold water is desired, the faucet handle is thrown in a reverse direction, causing the water to flow through an unheated by-pass. The machine can heat about 30 gal. an hour, using either direct or alternating current.

Joins Rudel-Belnap

MAJOR T. E. Ryder, D.S.O., M.C., who has just recently returned from overseas after four years' service in France and Belgium with the Canadian Field and Siege Artillery, has been appointed general manager of the Rudel-Belnap Company, of Montreal and Toronto, with headquarters in Montreal.

MAJOR RYDER, D.S.O., M.C.

For over ten years prior to the outbreak of the war, Major Ryder was connected with the Canadian Fairbanks-Morse Company, and was in charge of their transmission business in Montreal until 1908, when he was sent to St. John, N.B., to open a new branch for the company, remaining as manager until he enlisted for overseas service in the fall of 1914.

Liners 1,000 Feet Long

EVIDENTLY the race for the blue ribbon of the Atlantic is not to be dropped. From Washington, D.C., comes the announcement by the United States shipping board that two vessels are to be built which will have larger dimensions and greater speed than any liner afloat. Their length will be 1,000 feet, beam 102 feet and depth 74 feet, with a gross tonnage of 55,000. The passenger accommodation will be for 1,000 saloon passengers, 800 second cabin and 1,200 steerage, while the crew will number 1,000. The vessels will be of 100,000 H.P., oil burning, and will have enough fuel capacity to enable them to make a round trip without taking in fuel. They are designed with a view of becoming commerce destroyers in time of war, and will have gun emplacements included in the structure.

Nothing is mentioned about the draft of water that these vessels will require, but it is significant that they will have a terminal at Montauk Point, 118 miles from New York city. The depth of the Ambrose Channel is forty feet, and a vessel of the size mentioned would have nothing to spare there. The "Lusitania" drew 35 feet 2 inches. This is the factor that limits the size of vessels more than any other. It is no use building a vessel that cannot find a harbor to go into, or that cannot be dry-docked owing to the lack of a dock large enough to take her. The question of speed involves two considerations, the one being the increased consumption of coal, and the other the saving in maintenance of passengers and crew by being one to two days less on the voyage. First cost is greater for the higher speed vessel owing to the greater weight of machinery required. If these ships are built it is quite likely that they will hold the laurels for some time, as the building of ships of extraordinary speed and huge dimensions is not likely to be attempted by other nations at present. These vessels are always a good deal of a luxury, and are almost invariably heavily subsidized by their Governments. The large-sized, moderate-speed vessel is another proposition, as space that is devoted to machinery in the high speed ship can be utilized for profitable purposes, the fuel consumption is considerably less, and the difference in time occupied not amounting to more than about 18 to 24 hours.

MARKET DEVELOPMENTS

Strike Settlement is Good Piece of News

Tool Room Output is Needed in Several Cases—Industries Have Decided to Go Ahead With New Lines—Metal Market Showing Great Deal of Strength in Many Lines

THE announcement that the machinists' strike has been concluded in Toronto and district is naturally good news to the machine tool trade. It may take some days to get things under way in some plants, but work will be facilitated in many ways in a short time. Tool room output is needed in several cases where new lines are contemplated. It has been necessary in some cases to send across the line for this, causing delay at a very inopportune time. Not only so, but several firms have changed the decision of some few weeks ago to shut down for the remainder of the season, and will, as soon as mechanically possible, go ahead with the turning out of new lines that should have been placed on the market this season. It will require some little confidence, but the decision has been made to go ahead and manufacture now, trusting to a vigorous selling campaign later on to see them safely through.

"The best week this year," was the manner in which one leading machine tool dealer referred to the business closed by his house during the past few days. The fact is that those who were waiting for lower prices before coming into the machine tool market are being left with very indefinite delivery dates and at prices higher then they could have secured shortly after the signing of the armistice. Increases have been made in several lines. In one case in particular quotations that were made to a large Canadian concern on chain blocks have been withdrawn. The figures were given in the middle of June, while now an $87 article has gone to $112, and others in proportion. Reductions have been made on high speed cutters, both Canadian and U.S. makes.

Buying of supplies is improving. The National railroads are in the market this week for 1,500 carbon drills and about 50 of the high speed variety.

The scrap metal market is showing exceptional strength. Machine scrap is very scarce, and the higher figures are not bringing out any offering to amount to anything. It was thought that war shop material would come in under this. It may be that higher prices will have to be offered. Coppers continue strong, and a slight advance has been made in tin for the first time in some weeks. Mills and foundries are buying heavily of scrap material, as many of them had bare yards, waiting for conditions to become a little more settled before stocking up.

CONFIDENCE MORE MARKED IN TRADING IN MONTREAL MARKET

Special to CANADIAN MACHINERY.

MONTREAL, Que., July 31.—We have all been looking forward for the turn in the tide that has been promised as a result of the signing of the peace treaty, but the change has been so gradual that it cannot be rightly said to be a turning point.

From every angle comes reports of better business; steel interests are encouraged by the better feeling that prevails, although no heavy buying is taking place. Sales of plates and shapes have shown a slight increase, but little attention is given to future requirements. Salesmen are again coming into their own and the question of the disposal of materials is again to the fore. Consumers are less concerned about delivery now but are reluctant to buy heavily for future needs. Machinery dealers are encouraged by the steady return to normal business. One large machine tool house here has established a well-equipped machine shop for the repair and rebuilding of used equipment. Sales of new tools are gradually increasing. A phase of activity that tends to keep metal shops active is the fact that manufacturing rights are being obtained in Canada for English and American lines, many of which are being assembled in a plant apart from those in which the various parts are made and machined, frequently several places being employed for turning out the work for the assembly shop. The metal market reflects the general activity in the better demand and higher prices quoted.

Old materials are moving more briskly and advances are general on a very strong market.

Better Demand Puts Metals Up

The anticipated requirements of Germany and Austria in respect to copper have had no direct effect on the present market, but the possibilities in this direction are undoubtedly an unconscious factor in the remarkable strength of copper. The export prospect, together with the fact that domestic demand is steadily growing, are the two prime factors in returning copper to the position it held during the last year of the war. One dealer here stated that he considers copper reasonably cheap at the existing price, in face of the general conditions that prevail in all circles. It would not be a surprise to him to see copper go still higher. Tin is quite active just now and although a better volume of metal has been coming into Canada, the consumption has apparently equalled the supply. The restriction on the imports that has been in force in the States since the termination of the war may soon be removed, as it is thought that the Government has disposed of nearly all the surplus metal held over since war demand ceased. This change will probably open the way for many months, but no sharp decline is expected here; in fact it may mean a stronger market here for a short period until a balance has been struck. Local price on tin is 57 cents per pound, a 2 cent advance on last week. Business activity generally is responsible for advances in other

metals. Spelter is up ½ cent, the quotations being 10 cents per pound. Lead at 7¼ cents is ¼ cent stronger. Antimony is up 1 cent, the price quoted being 10½ cents per pound.

New Demand Increasing

Activity in machine tools is gradually returning to a basis when competition is a contending factor. The volume of business is far from that of a year ago, but is of a kind that tends to stabilize the market. Whereas the average war demand was for machinery contracts running into hundreds of thousands of dollars, the wants of the manufacturer today are on a much more conservative basis, but the distribution is over a much greater area. This, in itself, is a more encouraging feature, as it indicates a steady return to normal conditions. Sales of second-hand equipment are still in front, but the percentage is gradually swinging around. The relative ratio at present is approximately 60 per cent. on used and 40 per cent. on new equipment, with the latter constantly increasing. Demand for supplies is steadily growing better, and confidence in the trade is much more general. One dealer here stated that during the next few months they expected business would pick up considerably.

Scraps Advance to Higher Levels

Without question the situation in respect to scrap conditions is of a very firm character, and the general movement of material, both buying and selling, is of considerable volume at the present time. Emphasis, however, may be placed on the fact that purchases by the consumer are principally for early requirements, future needs receiving little consideration. During the past week it was announced that several thousand tons of scrap was to be shipped to Britain in the space reserved for Government purposes. It seems that this material is war supplies, owned by the Government, and in some instances the scrap is in the form of finished and semi-finished shells. The entire market is featured by higher prices, the upward trend in copper and brass scraps being a special factor. The advance in copper during the past two weeks has been approximately 4 cents per pound, the present range being 17 cents for light, to 21½ cents for heavy and crucible. Brass scraps also show sharp advances, new cuttings are quoted at 13 cents, red brass turnings at 16 cents, yellow brass turnings and medium brass at 10 cents, and light brass at 9 cents per pound.

Galvanizing demand has caused zinc to go higher, an advance of 1 cent placing the present price at 6½ cents per pound.

Advances on iron and steel scraps are likewise general, the range being 30 cents per ton on machine shop turnings, $8 per ton on rails; the quotation on the latter being now $20 per long ton. Other advances will be noted in the selected market quotations.

POINTS IN WEEK'S MARKETING NOTES

Pittsburgh reports an increase in the volume of steel buying. Plate is the only spot where added strength is needed.

—

Some of the U. S. mills are quoting iron rods $5 per ton up. This will affect the wire mills very quickly.

—

The demand for semi-finished steel has been good. In fact some of the mills are out of the market for ingots and billets.

—

Scrap metal prices are strong. No. 1 machinery scrap is very scarce and the offerings for this are likely to go higher.

—

Tin for the first time in some weeks took a rise this week.

—

Copper continues to go up, both for scrap and new metal.

—

Montreal reports a much better feeling in trading, and buying well distributed over a large number of industries.

—

"The best week this year," is the way one machinery dealer sized up the trading of the past few days.

—

Many of the U. S. machine-tool makers are insisting that selling prices now shall be the price at time of delivery of the machine.

MUCH BETTER TONE IN MARKET

Dealers Report Selling as Improving—Metals Are Stronger and May Go Higher.

TORONTO.—For midsummer weather there is a good volume of business on record in this district. Buying is becoming more general, while a lot of prospective business and enquiries have been converted into orders during the week just closed.

The practical settlement of the strike in this district, while not having an immediate effect, will be felt before long. There is a danger that in some lines it will not be possible to recover this season as the time for selling and organizing the seasons' work has gone too far past. In other cases it is known that work will be started just as soon as it is possible to get the men working.

Selling Was Brisk

"We have closed the best week's business this year," is the way one manager sized up the situation. In this case the buying was more general than has been the case for some time. The orders did not come from any particular line, but were well distributed. Railroad equipment, automobile shops and other lines were represented in the lot.

There can be no doubt that the machine tool market is rising. This paper has no purpose in saying so apart from recording what has actually taken place. Some dealers announce a general ten per cent. increase. Some of the less wanted lines are not affected. Deliveries on new equipment are none too good, neither are they showing signs of improving. It may be a small exaggeration to say that a situation somewhat similar to the war period is approaching, but there are several ways in which such a claim can be justified. The machine tool builders, in many cases, have no stock on hand. They are working under high costs which are constantly increasing. They cannot promise deliveries, neither can they guarantee prices on delivery.

A representative of CANADIAN MACHINERY saw three letters that came to Toronto this morning from well-known firms in regard to various lines they make. The idea in all was the same, viz.: that they would not guarantee any quotation made after this date. The only thing to do is to give a price on the date of shipment. This applies to many lines. For instance chain blocks are up far above their pre-war figure. One Toronto firm quoted an Ontario motor company on a lot of these in month of June. Since then they have been advised that the price is cancelled. The Toronto firm was to-day trying to hustle the buyer a little in order to see if the old price could not be secured were the order placed at once. Nor was the increase a slight one. Equipment that was quoted at $87 will now be worth around $112. It is worth noting that chain blocks are still far in advance of old prices without any additions being built on the prices. They are coming more into use as labor-saving machinery is put in, and a shortage of labor and a desire on the part of the shops in many cases to make work lighter and more agreeable is leading to the installation of labor-saving devices. In pre-war days chain blocks used to sell at 25 per cent. off the list, while now the quotation is double the list and 25 per cent. on, 250 per cent. more.

The Matter of Exchange

One big Toronto house is using a rubber stamp now, and it reads as follows: "Owing to the increased rate of exchange it is necessary for us to charge, as extra, prevailing rate on all American goods at time of invoicing." The exchange, which is to-day around 4½ per cent., is coming more and more as a factor in trading. There are some instances where it is quite an item in favor of stocks that have been built up here when the rate was at a much lower figure.

Expect Improvement

The machinery trade looks for an improvement with the strike of the machinists in this district practically disposed of. There is one case in particular where the program for the year is going to be proceeded with, although it was

seriously thought the best thing would be to close up for the remainder of the season. However, the management has decided to go ahead and make the line decided on and then turn the sales force loose on the proposition. The opening up of these machine shops is going to make business better not only for the selling of machine tools but for the supply business, which for some weeks past has been lacking in the assistance it usually gets from the wear and tear of the daily grind.

Cutters Are Down

A considerable reduction has been made in the price of Canadian and U.S. high speed cutters. It is hard to state in terms of per cent. just what the cut has amounted to. In fact reckoning up just what did happen is rather a laborious piece of business, but it runs something like this. Previously a 3x2 high speed cutter has bee nselling at list, plus 2½ times the extra, and now the price is list plus one and a half times the extra. Now that sounds simple enough, but it works something like this on the size indicated. The list is $9 and the extra is $5.75, and two-and-a-half times that and you have $14.37; add in the original nine and the price for the Canadian drill is $23.37; for the U.S. product add another forty per cent. of the total, and it comes up to $32.71. The present method of reckoning takes the $9, adds $8.62 and comes to $17.62 for the Canadian product as against a former $23.37. It may be very convenient to keep the price list the same and simply change the extras on or off, as the case may be, but it is certainly not as plain a way of marking goods as sticking a 25c sign on a box of men's socks.

The Canadian National Railways are in the market again for a nice line of material. Their last inquiry is for small tools, mostly carbon drills. The total list calls for about 1,500 of these, while the list is completed by some 50 high speed drills. This is a nice list and the supply men are figuring pretty close on it.

The Scrap Metal Market

The scrap metal market in this district seems to be coming into better days. Certain it was that there was a long period of wandering in the wilderness after the war. Those who have bought right have had a fairly good chance to clean up on the situation, and a stiffening price always has a good tendency on the market. When prices look pointed upward those who have material are more inclined to sell, while those who need shipments are anxious to get into the market and have their requirements covered before another rise takes place. Buying seems to be quite general, although the steel interests are not taking on a great deal yet, their wants probably being well looked after for some time to come.

There has been no further change in the prices, and they stand where they were placed a week ago, but there is no getting away from the fact that there is more business moving. Machinery scrap, No. 1, is scarce, and it looks to be a safe guess that there will be a better price offered for this before long to see if it will have the effect of bringing any there may be into the market. It is not coming out at present quotations. There are a number of shell shops in the country yet that ought to furnish something for this class, although no doubt the hope is entertained that a sale for second hand machinery might be more advantageous. Some transportation concerns that had been holding back their offerings in hopes of better figures let go during the past week, and some good tonnages have been brought in from this source.

Coppers continue strong, and it looks as though the market for scrap metals of this sort might be marked up slightly before very long.

The Non-ferrous Market

There is a good demand in the market for all classes of materials and the trend is upward, finding vent in a higher rating for tin, copper and spelter, although there is a slight reaction in the price of the latter just now. Copper is quoted locally at 27c to-day. Tin, for the first time in some weeks, starts upward, making a 4c advance.

DEMAND IMPROVES FOR STEEL EVEN DURING THE SUMMER MONTHS

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., July 31.—The American Iron and Steel Institute has just given out the complete statistics of production of steel ingots and castings, rolled iron and steel, etc., in 1918. These statistics put the matter in a somewhat new light, by reason of the divergence between production of ingots and of rolled steel. During the year the trade had the benefit of monthly reports of the steel ingot production, and last April a preliminary statement of the year's total was given, agreeing almost precisely with the final total now given. It turns out, however, that the rolled steel output was a much smaller proportion of the ingot output than usual. This was due, of course, to the heavy cropping of ingots required by shell steel specifications, but so much was said about uses being found for discard steel that one had some reason to suppose that this heavy cropping would not operate to decrease greatly the production of finished rolled steel. If, for instance, one-third of the ingot was cropped, that steel would be lost as regards shell material, but if it was rolled into light rails, or angles for cots, or concrete reinforcing bars, it would constitute rolled steel. The fact, however, is that while in 1912 and 1913 the total output of finished rolled steel was 76 per cent. of the steel ingot production, in 1918 the proportion was only 69 per cent. That difference of 7 per cent. meant, on the 43,051,022 gross tons of ingots produced in 1918, no less than 3,000,000 gross tons of rolled steel, or 250,000 tons a month. This information helps to explain, to an extent, why the director of steel supply found the supply of steel so much below what he wanted, when nearly every month the statistics of ingot production seemed rather favorable.

The production of ingots in 1918 was 1 per cent. under that of 1917, while it was 4 per cent. above that of 1916. Thus the three great war years ran quite closely together. The 1918 production was 42 per cent. greater than the production in 1912 and 1913, years that showed practically the same tonnage, and by far the best tonnage years before the war. The rolled steel output in 1918 was 29,581,778 tons and the rolled iron output 1,573,976 tons. The rolled steel output was only 28 per cent. more than the 1912-13 output, while the rolled iron output actually showed a decrease of 5 per cent. from these pre-war years. The total of the two was 26 per cent. greater in 1918 than in 1912-13, while ingots showed an increase of 42 per cent

The production of sheared plates, ¼ in. and thicker, was 3,445,284 gross tons, or more than 2,000,000 tons increase over the 1913 output. This was due to the pressure for ship plates, and the increase was accomplished only by the building of many new plate mills. Some of the mills, however, were not completed until nearly the end of 1918, and thus the present capacity is much larger even than the heavy output in 1918. Undoubtedly there will be a surplus of plate rolling capacity for many years.

Production of shell steel is not shown in the statistics. The rolled rounds are included with "merchant bars," which showed a gain in 1918 of about 2,500,000 tons over the 1913 output, while the steel for forged shells was included with "rolled forging blooms and billets," which showed an increase of over 1,000,000 tons. As there was no other demand of importance that would swell the production of either merchant bars or forging steel, it may be assumed that the production of shell steel in the United States was somewhere in the neighborhood of 3,500,000 gross tons.

Other lines of rolled steel showed about the same tonnage in 1918 as in 1912 and 1913, except that some showed rather sharp decreases, rails, for instance, falling off about a million tons, to 2,540,892 tons.

Present Production

Production of steel ingots at present may be estimated as being at the rate of about 35,000,000 gross tons a year, which would be 71 or 72 per cent. of capacity, taking capacity at 49,000,000

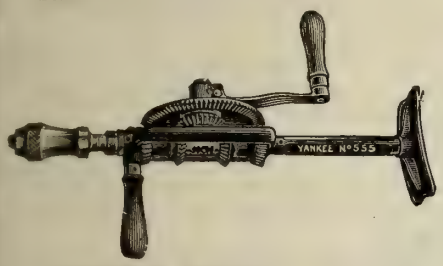
SALES SUPPLY DEPARTMENT SERVICE

MORE AND BETTER WORK

More and better work can be accomplished in garage, manufacturing plant or machine shop by the adding of time-saving tools. Tools that are always ready when required. Are real necessities in the plants that are making good under the stress of getting there in the winning of satisfied customers.



YANKEE BREAST DRILLS

TAPS AND DIES

The Garage or Machine Shop will find an inexpensive outfit that pays many times over its first initial cost. Obtainable in A.L.A.M., U.S.S. and "V" threads, having adjustable Dies. No work is out of range. Make your equipment complete with one of these sets.

CHUCKS

IMPERIAL CHUCKS are Canadian made and will meet the best expectations as to accuracy and ability to meet all conditions required of strong up-to-date chucks. These chucks will compare favorably with any chuck made of the four jaw Independent type.

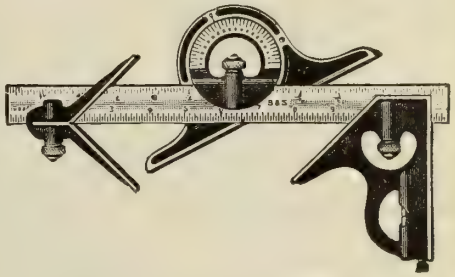
YANKEE TOOLS

No tools have advanced to meet the modern demand like YANKEE Tools. They are complete in every respect. Quality, workmanship, are always of first consideration in these tools. Once used they are found to be an absolute necessity, and are money and time savers many times over.

BROWN & SHARPE, AND STARRETT FINE TOOLS

Delivery on these tools still covers a period of six months to one year. Therefore, we would advise your ordering immediately. Machine manufacturing is fast coming back in a large way and the skilled mechanic will find it to his advantage to get our prices and look over our stock of the well-known Brown & Sharpe and Starrett Tools.

REECE'S SCREW PLATES

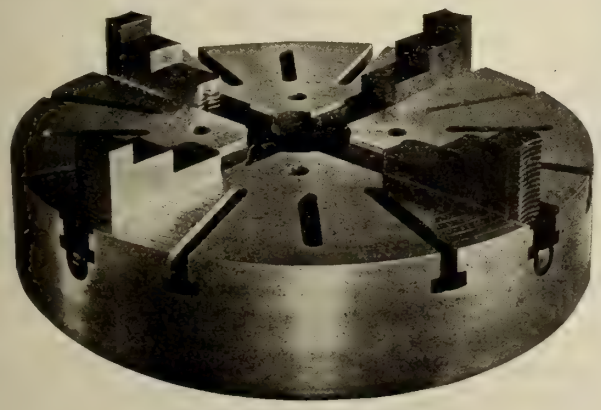


BROWN & SHARPE AND STARRETT MECHANICS' TOOLS

REED VISES

If there is a well known vise—it is the REED Vise, manufactured as it is under rigid inspection it is thoroughly guaranteed against defective or imperfect workmanship, and will unhesitatingly be replaced if it can be returned defective.

These vises are interchangeable and have been standardized by many of the large manufacturing plants. Your safety is in the REED vise.



IMPERIAL CHUCKS

REED VISES

Prices and No. 40 Catalog will be cheerfully given on request.

THE A. R. WILLIAMS MACHINERY CO., LTD., TORONTO, ONTARIO

tons. While a 35,000,000 ton rate would show quite a decrease from the 43,051,022 tons actually produced in 1918, the output of finished rolled steel would not show a corresponding discount, for it may be assumed that the proportion of rolled steel to ingots is back to the 76 per cent. recorded in 1912 and 1913, and thus it would be equal to a rate of about 26,500,000 tons at the present time, this comparing with the output of 29,581,778 tons in 1918. The difference is less than last year's output of shell steel, and thus one may say that in all rolled steel outside of shell steel the present production is at a greater rate than the average of 1918.

Steel Demand

Demand is improving somewhat, even in this summer period, usually so dull in the steel trade. Merchant steel bars are mentioned in particular. For some time there has been heavy demand from the cold drawn steel makers, producing shafting and screw stock, and now there is much more widespread demand, the current orders being not much below capacity. Demand for butt weld sizes of pipe continues to improve. As for lap weld, the mills are turning away more business than they accept, being filled up on account of the oil boom.

Export demand is not as heavy as a month ago. The slump in exchange is probably responsible for some of the decline in European buying. Japan and China are still mentioned as being the best buyers. In their case there is no difficulty about exchange, and transportation conditions are particularly good as the Japanese vessels operate under quite favorable conditions. While the export market is somewhat quieter, it is not expected that there will be any material decrease in exports over the average of the past few months, exports having been reported at about 400,000 gross tons a month, in pig iron, billets and finished steel products.

Prices

The balance of probability is that there will be no general advances in steel prices in the near future. All possibility of there being declines is regarded as removed. It is true that a few independent producers have been disposed to advance prices, but such advances when made have not been followed by others. It was July 10 when the Wheeling Steel & Iron Co. advanced butt weld pipe $5 a ton, and lap weld pipe $10, but up to date no other producer has advanced pipe. A fortnight ago the Youngstown Sheet & Tube Co. advanced nails 25c a keg, staples $2 a ton and the extra for coppering wire $5 a ton. A few days afterwards the Cambria Steel Co. made some advances in its wire products, but not the same advances as had been made by the Youngstown Co. Cambria advanced both polished and cemented coated nails 25c a keg, but also advanced plain and barb wire $2 a ton, products which the Youngstown Co. did not advance at all. The Steel Corporation continues to be opposed to the making of any price advances, at least before the end of the year.

MORE FURNACES ARE BEING BLOWN IN TO SUPPLY THE DEMAND FOR IRON

INQUIRIES and sales are brisk, some large orders having been booked during the week. Orders and shipments are generally beyond present production. Following are reports:

Pittsburgh.—Steel makers are coming to the furnaces for bessemer pig iron, and the indications are that the stocks on hand are being worked out. Sales of foundry and basic are limited. The Carnegie Steel Co. has blown in four furnaces during the past week.

Boston.—Sales are generally small, only one lot of any importance having been sold. Enquiry remains good. Total sales for New England for the week are around 7,000 tons. Enquiries for 1920 delivery are meeting with no response from the furnaces.

New York.—Last week's business for foundry iron was in the neighborhood of 25,000 tons, for this year's delivery. The New York Airbrake Co. placed orders for 10,000 tons. Numerous enquiries are out, with the result that the market has developed a strong tone.

Buffalo.—Furnaces are in a position where they are not looking for any business for the balance of the year. Two furnaces are booked up, and the others have only very small capacity left.

Philadelphia.—There is a good enquiry here, and some consumers are asking quotations for 1920 delivery. Furnaces are not keen about selling so far ahead. About 15,000 tons of foundry were sold during the week. Prices are very firm.

Cleveland.—With sales and shipments running ahead of furnace production, furnace stocks are getting low. One dealer sold about 32 000 tons last week, largely foundry, and about 6,000 tons of this were for 1920 delivery. An enquiry for from 50,000 to 75,000 tons basic came out during the week.

Cincinnati. — Southern furnaces are mostly quoting the regular schedule of $28 for this year's shipments. There is not much enquiry, but a buying movement is expected, with an advance in prices before long.

St. Louis.—There is a fair demand for small lots, sales averaging about the same as the past two weeks. Steel makers are not in the market, except for small lots of special grades for mixtures. Most consumers are covered for this year. Furnaces are waiting for higher prices before blowing in idle stacks.

Birmingham.—Stocks are being depleted rapidly in this district, and while sales are not large, prices are firmer. Production is being increased, and three more stacks will be repaired immediately.

Chicago—More stacks are being blown in, and six merchant stacks are now in operation. There has been an increase in the demand for pig iron. Labor troubles are having their effect on sales, as it is felt that were it not for this, some consumers would buy more heavily.

HEAVY MELTING IS IN DEMAND AND SCRAP VALUES ARE GOING UP

Buying is active all over the country and prices are rising accordingly. Following are reports from various centres in the United States:

Chicago.—Prices on all grades of scrap are rising, to the amount of $2 to $3 at a time. Heavy melting steel is expected to reach $25, and rerolling rails $30 per ton before the end of the year. Rolling mill grades are in good demand.

Boston.—Activity in steel making grades is in evidence, and the start of a buying movement has improved the tone of the market. Prices on all grades have advanced. Heavy melting steel has been sold at $20, and turnings have brought $11.

New York.—There is not a very active market, but there is a fair demand for most grades, and prices are holding firm, with a tendency to rise. Heavy melting steel has been sold to Pittsburgh buyers for $20.50 delivered, and is quoted $15.50 to $16 f.o.b. New York.

Philadelphia.—The market here is a little soft, with material in plenty, dealers buying only for shipment. Machine shop turnings and cast iron borings now quoted at $13.50 to $14.50.

Pittsburgh.—With heavy melting steel selling at $21.50, dealers are hoping to see it reach $25. Other steel making grades are active and firm in proportion, but foundry iron is only in small demand. Steel car wheels are quoted at $21.

Buffalo.—All steel making grades are in strong demand, dealers asking $18.50 for heavy melting steel. Mills are offering $18. Low phosphorus is quoted at $22 to $23.

Cleveland.—The market here is strong and active, demand for heavy melting steel, turnings and borings being particularly strong. Prices on all grades have advanced. Heavy melting steel is quoted at $21, with borings $15.50.

Cincinnati.—Steel mill scrap and cast scrap are in good demand, and dealers have advanced quotations on all grades. Considerable steel scrap for this year's delivery has been bought by semi-steel foundries.

St. Louis.—The market here is confined to transactions between dealers, the large consumers having good supplies. The Government are offering about 5,500 tons low phosphorus and shell ingots.

Birmingham. — Domestic market is weak, but an enquiry for heavy melting steel for export aroused considerable interest. Prices are softening, but slightly.

Aikenhead's
TAYLOR PORTABLE STEEL DERRICK

CONSTRUCTED OF MALLEABLE IRON AND STEEL

LIFTING CAPACITY
1,800 lbs.

WEIGHT 197 LBS.

This derrick is tested to hoist 1800 lbs. One man can operate it, but two, or even three men can man the cranks when desirable.

It can be used for hoisting building and roofing material, unloading railroad cars, hoisting ice, stone, marble, machinery, loading waggons, handling baled hay, and for any purpose where the load is required to be hoisted and swung. It swings a complete circle and is equipped with brake to control block.

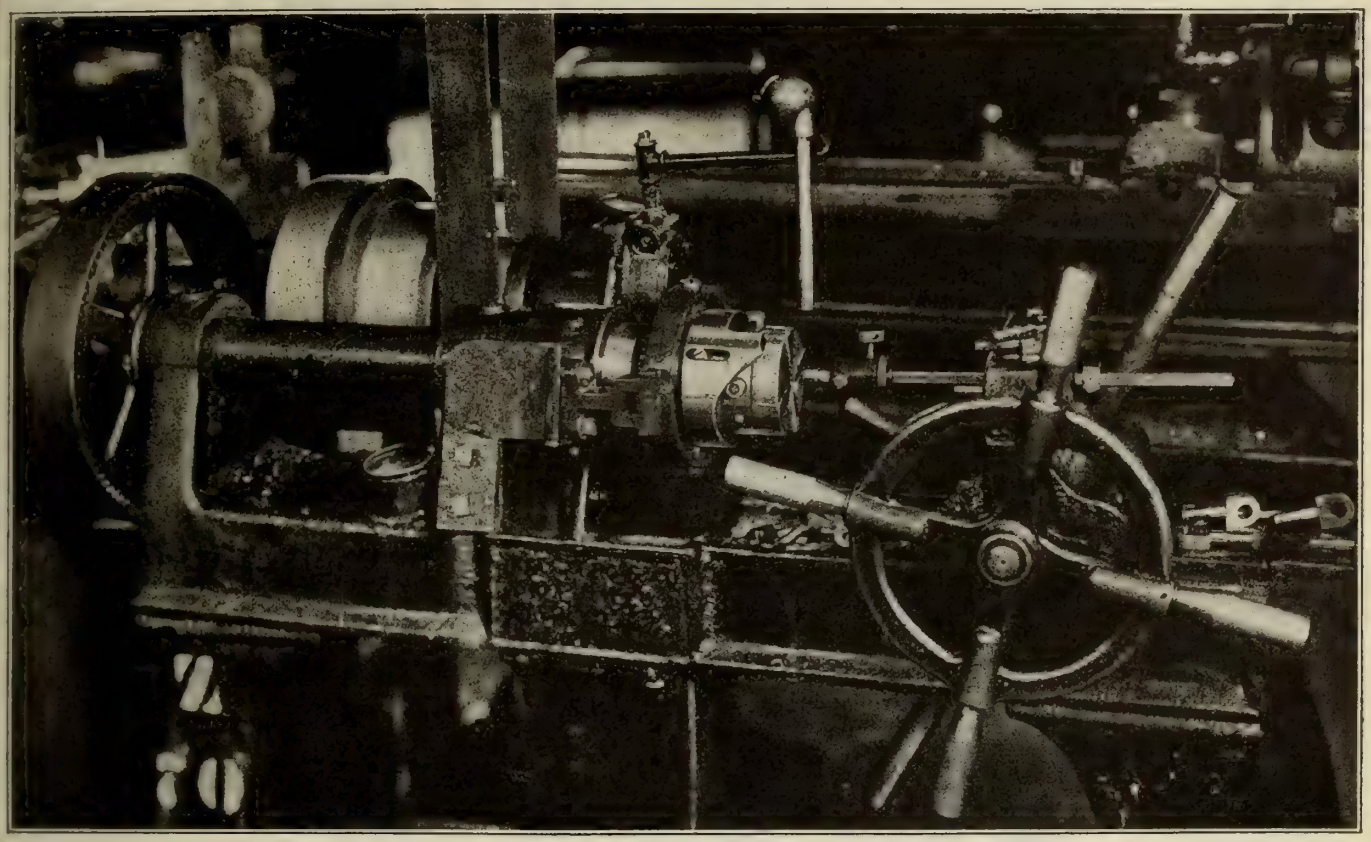
BROUGHT UP TO DATE



This old Bolt Cutter has been turned into an up-to-date Threading Machine by the application of a Geometric Die Head.

The Connecticut Telephone Company removed from this Bolt Cutter the solid die head with which it was equipped, and put in its place a Geometric Self-opening Die Head of the type regularly furnished on the Geometric Threading Machine.

Thread is 7-16″ diameter, 14 U.S.S., about 1″ long, on switchboard terminals of a high class copper casting.

The best part of it is, that besides getting clean, sharp threads, they have increased the work about six times over what was being accomplished with a solid die head.

Has any threading operation been given the right chance unless a Geometric figures in it?

The Geometric Tool Company, New Haven, Conn., U.S.A.

MILWAUKEE MILLING MACHINES

Double Overarm maintains alignment.

It is impossible for the operator to place the arbor supports on the arbor and double overarm in any other way than in line. Arbor cannot be pounded out of line when using large, coarse pitch cutters on rough, heavy work.

Other Distinctive Milwaukee Features:

Solid top knee—hardened steel gearing and shafts in the column and feed box—automatic flooded lubrication — one and one-half gallons of oil per minute pouring over all gears and bearings in the column and feed box, insuring lubrication at all times—flanged spindle with hardened steel collar for driving arbors—constant speed drive, reverse being self-contained.

Send for our No. 21 Catalogue. Illustrating and describing Milwaukee Milling Machines and accessories in detail

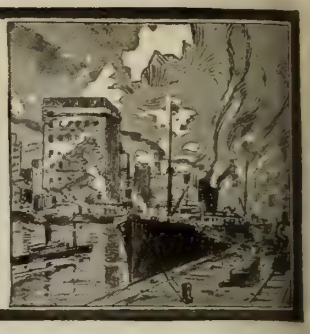
INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES



TRADE GOSSIP

To Extend Restrictions. — Premier Lloyd George, in a speech recently, said it was impossible to put into effect the Government's trade policy. He therefore urged that the trade restrictions expiring in September, be extended to a future date.

Newmarket Lets Contract.—The Town Council, at a regular meeting, awarded the contract for a new bridge at Prospect Street to Mr. Lewis of Toronto. The cost of the bridge will be $3,000. A cement bridge to replace the wooden one on Queen Street was discussed, but no decision was reached.

To Relieve Congestion.—The British authorities, in an endeavor to relieve the congestion at the leading shipping ports, are introducing a new rule. All heavy cargoes consigned through ports where congestion is being experienced to destinations that can be more easily served through other ports will be transferred to coastwise steamers at once.

High Prices for Timber Limits.—Some of the Ontario timber land sold recently brought the highest prices ever received, according to the Hon. G. Howard Ferguson, Minister of Lands, Forests and Mines. These lands were situated along the northern shores of the Great Lakes. The highest price obtained was $22.50 per 1,000 feet on the stump, while a number of lots brought $20 per 1,000 feet on the stump.

Take No Ads.—The British Board of Trade desires to state that announcements which have been made in various quarters in the press that advertisements are to be accepted for the "Board of Trade Journal" are entirely without foundation. It was announced in September, 1917, that no advertisements would be accepted after the current contracts had expired, and no change has since been made in the policy of excluding advertisements.

New Cyanide Plant for Canada.—The Cassel Cyanide Company, Ltd., of Glasgow, Scotland, are about to incorporate a Canadian branch of their company. This is on the recommendation of their manager, Mr. Neill, after making one of his periodical tours of Canada and Mexico. He was very favorably impressed with the mineral resources of Northern Ontario and the industrial possibilities of the country generally. The board of the Canadian company will have three members from the Glasgow board, and Mr. Neill will divide his time between the Canadian firm and the parent company.

Foreign Trade Committee.—The Western provinces are anxious to have a foreign trade commission to represent them exclusively, as they believe that to build up western industry a proper investigation of foreign markets is necessary. The idea originated with Mayor Brown, of Medicine Hat, who is president of the Alberta Industrial Association. Mayor Brown sees the possibilities of trade development across the Pacific, and points out that one-seventh of the population of the globe lives along the banks of one river in China.

Double Tracking Railway.—The Canadian Government Railways have let contracts for the double tracking of the track between Halifax and Moncton, and for a section in New Brunswick and one in Quebec. In Nova Scotia the track will be doubled from Truro to Belmont and for long stretches from Maccan and Springhill Junction. A section is to doubled from Moncton towards St. John and at Ste. Rosalie in Quebec. The contractors are the Cook Co., Bate McMahon & Co., and M. J. O'Brien.

International Patent Bureau. — The patents section of the International Research Bureau now sitting at Brussels, have agreed on the establishment of an International Patent Bureau. This would not interfere with the working of any country's patent law, but would work out in this manner: An inventor would take out patents protecting his invention in his own country and then apply to the International Bureau for protection in every other country. This would greatly lower the cost of the desired protection and be an immense advantage to inventors the world over.

Machinery Coming Back.—German industrial firms who had set up stolen Belgian machinery in their own factories are now being compelled to disgorge their ill-gotten plant. About 3,000 tons weekly of this machinery is being shipped back to Belgium, the total tonnage returned on July 1 being 18,000. Regulations for trading with Germany will be issued in Belgium shortly, every transaction being required to be under license. Importation of raw material from Germany will be encouraged, and finished products that do not compete with Belgian manufactures will be allowed.

Useful research.—The research department of Sir W. C. Armstrong-Whitworth & Co., Ltd., have succeeded in producing bronze and aluminum powders, which are so largely used in finishing work on liners and other ships. Before the war the production of these powders was practically a German monopoly. It was only after prolonged experiment and research that the powders were evolved. The powders form bronze and aluminum paints, which are heat resisting, non-corrosive, and giving a beautiful finished appearance. The aluminum powder is also used in steel making. Almost any desired color can be obtained.

Heavy Demand on Lumber Stocks.—Stocks of lumber in Ontario are at a very low ebb, and it is confidently predicted that all stocks will be exhausted by the end of the year. In order to counteract this the cut will be started so much earlier this year. Though the British Columbia mills are again working full swing the demand is greater than the suppiy. Ontario can use all the lumber she can cut without exporting any, and it is a fact that United States buyers looking for lumber in Ontario have found that Ontario was looking for lumber in the States.

Getting After German Business.—British and French business men have been passing through the Rhine bridgeheads for the past three months, intent upon establishing commercial relations which can be taken advantage of when normal conditions are in force again. The British and French military authorities have given free permit to their business men in passing through, while the American authorities have refused all access to Germany through the bridgeheads controlled by them. This has given the other nations a long pull in getting the German trade.

Enjoying a Boom.—Furniture factories in Canada and the United States are booked up for months to come and with a purely domestic demand. Now the demand for export trade is opening up and manufacturers foresee a still further elevation of prices. Furniture now costs about 50 per cent. more than it did in 1918, and about 100 per cent. more than in 1914. Dealers state that cheap furniture is practically unsaleable, the cheaper kinds of wood not being wanted. Suites that could not have been sold in 1914 are now readily got rid of, and the great trouble is to buy fresh stock to replace them. The only failures that have occurred in the furniture business during the last few months have been in houses handling the cheaper grades.

FEDERAL ENGINEERING CO., LIMITED
172 John St., Toronto

Opportunities for Export.—Mr. A. C. Mambert, the Ontario Timber Commissioner in London, says there is a good opportunity to export wooden pails, rakes, brooms, washing machines, trays, paint brush handles, etc., from Ontario to France and England. There has been some trade along these lines done, but in a desultory fashion. Before the war Germany had the command of this trade, with Sweden and the United States following. At present importations into England are prohibited from any country outside the Empire, or else are subject to license, which is difficult to secure. There is a great chance right now to get into this trade on a sound basis.

Going to Preston.—Purchase of the Preston Chair Company by the Canada Last Company of Toronto was effected recently. The chair company has been in liquidation, and the town of Preston was obliged to take over its liabilities. The sale of the plant to the Toronto firm will enable the municipality to recover its loss. The Canada Last Company has made its product from blocks, but when the newly-acquired plant is in operation a sawmill will be included in the equipment, and the blocks will be cut from the log. The Council of Preston is congratulating itself on securing a new industry to replace the Preston Chair Company.

The Cost of Coal.—The wild rumors that coal will jump in price as much as $5 to $6 a ton, and a famine develop during the winter, are discounted by Canadian coal dealers, who have been looking into the situation in the States. There will be a shortage, it is thought, and probably a small rise in prices, but nothing like the rise that has been freely prophesied. If people get panicky and all rush to buy coal at the one time there will be a fictitious situation created which will tend to elevate prices. Many of the Italian laborers are returning to Italy, which is creating a shortage of labor, naturally affecting the output. There will be enough coal available to face a normal winter is the consensus of opinion.

Better Wages at Beginning.—Manufacturers who are alarmed at the way young men are taking to the lower or unskilled classes of work because of the better pay to be obtained by a beginner, are considering a way to combat this tendency. Their idea is to pay a beginner at a skilled trade more than he is actually worth in order to encourage him to stick with it and eventually become a skilled mechanic. They believe in this way that they will get permanent men and save the large amount of loss entailed when a skilled man leaves and a new one takes his place. Every man who runs a shop knows that, no matter how good a new man may be, he is a source of expense for the first day or two, or possibly longer, till he becomes habituated to the practice of the new shop.

High Price of Hides.—The prices of hides and leather are now practically sky high, and the supply in the United States and Canada is so low that further advances seem inevitable. Tanners are delivering leather at present at lower prices than they can restock at, and shoes are selling at prices which cannot be repeated on fresh stocks. The only thing that can check this advance would be increased imports. There are large accumulations of hides in Russia, and also in South America, India and China. What is wanted is increased transportation facilities. The stories that all raw material had been cleared out of Russia is evidently false, for a shipment of hides arrived at a Pacific port recently from Russia in excellent condition, nothwithstanding the fact that the hides were over four years old.

The Alien Getting Even.—The many aliens of supposedly Austrian nationality, but really Slavs and Croats, who have been working in the anthracite mines, are getting out of the country as fast as they can. Forty-two thousand have already gone, and as fast as steamer space becomes available, more are going. These men, who were far from being in sympathy with Austria during the war, resented the attitude displayed by many Canadians to them, and as a result of their being so anxious to get back to their own countries, there is a grave danger of many of the people who vilified them being cold this winter. The production from the mines, where central Canada gets her anthracite coal was, up till the end of June, only 38,000,000 tons, ten millions less than for the corresponding period of 1918.

The Coal Situation in B. C.—Sir Robert Borden sent a telegram to the mayor of Sydney Mines, which was read at a labor meeting recently. The Premier stated that the Canadian National Railways were taking more coal from Nova Scotia this year that last, and had divided their orders between sixteen different mines. He pointed out the handicap that Nova Scotia was under owing to the shortage of ship tonnage. He stated that the Canadian National now had a stock of coal on hand good for seventeen weeks and were adding to their stock daily. Mr. R. H. Butts denounced the leaders of the United Mine Workers locally as demagogues and agitators. Mr. McLachlan, addressing the meeting, was not disposed to accept the Premier's explanation and thought that much of the present unrest was due to the Government's attitude towards labor. He thought that United States coal should be shut out of Canada altogether.

Strike Ends.—About sixty shops in Toronto have resumed operations when the machinists, on strike for twelve weeks, returned. Following a conference between the employers and representatives of the men, the latter at a meeting accepted the terms offered with little comment, and were instructed to report for work at once. About 1,200 men started the following day. While it may be several days before all of these men are placed owing to the disorganized state of the shops following the strike, they will all be looked after. While the strike is generally admitted to be a failure in so far as the strikers did not receive the 44-hour week and 50-hour pay demanded, it is pointed out by union officials that these conditions, as well as the extra wages, have been conceded by twenty-three shops in the city at which the men have been working for some time past. The question of wages with the 56 shops will be settled at another conference between the union officials, the Strike Committee, and the manufacturers. One of the union officials stated that the loss in wages to the men might be figured as something well over a million, while the International paid out $560,000 in strike pay.

Increase in Express Rates.—The application of the Express Companies for an increase in rates has been dealt with in an exhaustive report from the Board of Railway Commissioners, occuping 93 pages of printed matter. The judgment admits that the companies are carrying on business at a loss, and in order to increase receipts, increases are allowed in the general merchandise list. There is no increase allowed in essential commodities, the Board considering that such an increase, however small, would afford a reason for a further increase of price in these commodities to the consumer. The Board feels that such a change is undesirable in the interests of the consumers and the express companies themselves. The increases allowed in the general merchandise scale amount as a whole to 45.94% on Eastern Canada, 23.75% on the prairies, and 1148% in British Columbia. The effect on the three different sections of the country will be as follows. The prairie rates 39.55% higher than Eastern Canada, will be under the new schedule only 17.88 per cent. higher, and British Columbia now 29.29% higher than the prairie rate, will be now only 15.01% more. The wagon service is materially increased in the cities, thus giving relief to those districts that have not formerly had an adequate service.

Cost of Pavement.—"That it is costing the city forty per cent. more to pave streets by giving the work to contractors than by the city undertaking the work," was the statement made by a member of the Chatham council. The alderman stated that in reply to an enquiry as to the cost of grading, paving and curbing at Gray and Lorne Avenue, made at the council, is proof of his statement. "It was shown by the figures that the cost of the work of putting down Gray Street pavement, not including material, is 16½c per square yard, and the cost of curbing was 15c per lineal foot," said the Alderman. "Adding overhead charges, which would not exceed more than 10c per square yard, it will readily be seen by these figures that the cost of laying pavements by city workmen, and under the city engineer, is about forty per cent. less than by contract, when we consider that on certain streets contracts have been awarded at one dol-

Building at Kitchener. — Construction of a plant for the assembling of motor truck parts and for the manufacture of truck bodies will be proceeded with almost immediately in Kitchener, according to an announcement by an official of the F. W. D. Auto Company, which will operate as the Canadian end of the parent organization in the United States. The decision to erect a plant in Kitchener was arrived at some time ago, and a site was purchased in the eastern section of that municipality. Difficulties arose in connection with the new location of the Grand Valley Railway, and it was found advisable to postpone the work of construction until the railway plans were completed. These details have been worked out finally, and there are no further obstacles to the immediate erection of the plant. Trucks have been shipped in from the United States plant meanwhile to fill Canadian orders. One of the considerations that governed the truck company in seeking to establish a plant in the Dominion was that the British preference on motor cars will make it advantageous to ship Canadian rather than American trucks. The markets of the Empire look attractive to this firm The United Kingdom is regarded as a promising field. Australia, New Zealand, India and South Africa, and all other sections of the British Empire where railway transportation is not highly developed, are looked upon as potential markets for large numbers of trucks. Production will be commenced at the Ontario plant before the end of the present season.

INCORPORATIONS

The Galt Brass Company, Limited, has been incorporated with an authorized capital of $500,000 to take over the liabilities and carry on the business of the Galt Brass Company Limited, Galt. They expect to develop and expand the business considerably. The old company was incorporated under a provincial charter, while the new concern has obtained a Dominion charter.

MARINE

Cleveland.—The death is announced of Capt. Charles A. Benham, master of the steamer John Stanton, of the Hutchinson fleet. He was only 51 years of age, and was in active service up to a week from his death. He is survived by his father, Captain C. E. Benham, and four brothers, besides a widow and two sons.

Paris.—The French Minister of Public Works, M. Albert Claveille, announced in the Senate that he would shortly submit a plan whereby France's mercantile tonnage would be increased to more than double the pre-war tonnage in the next three years. The aim of the Government would be to build 5,000,000 tons in French yards.

Hamilton.—A big appropriation having been made by the Dominion Government early in the year for work on the harbor, the Board of Harbor Commissioners are anxious to get it started. To this end Mr. T. J. Stewart, M.P., at-

ended the meeting and promised to use his good offices to get the work started as early as possible.

Rotterdam.—The N. Y. Wiltons machine factory, Scheepvart, has acquired a plot of land between Vlaardingen and Schiedam, for the purpose of building a huge dockyard. The dockyard will be used for building ships, which will be built in the dock instead of on slips. To begin with only one dock will be built, in which two ships about 650 feet long, and eight small ships, about 328 feet long, can be constructed at once. If the venture proves successful a similar dock for the construction of vessels as big as the Vaterland will be built, as well as a floating dock to take vessels of 40,000 tons. The dockyard, when completed, will be the largest in Europe.

NEW BOOK ON ABRASIVES

Abrasives and Abrasive Wheels

By Fred B. Jacobs

Three hundred and thirty eight 5 in. by 8½ in. pages, bound in dark red cloth boards. Published by the Norman W. Henley Publishing Co., 2 West 45th Street, New York, U.S. Price $3. This book is a complete treatise on the manufacture and practical use of abrasives, abrasive wheels, and grinding operations.

The natural and artificial abrasives are discussed fully, also the production and preparation of the same. Grits, grades and bonds, sharpening and grinding stones and wheels, testing wheels for efficiency, trueing, rebushing and installing wheels, safety devices, and dust-collecting systems, complete exposition on surface, external and internal grinding, and comprehensive data covering the physical and chemical nature of abrasives in general are fully explained and illustrated.

A condensed list of contents follows: Natural abrasive substances, artificial abrasives, the manufacture of grinding wheels, artificial sharpening stones, grits and grades, testing wheels for efficiency, laboratory tests, grinding wheel vs. grindstones, the economic advantage of using large wheels, trueing devices for grinding wheels, suggestions to follow in ordering grinding wheels, design of dust-collecting systems, safeguarding grinding wheels, abrasive papers and cloth, surface grinding, cylindrical grinding, internal grinding, special grinding operations, cutter sharpening and saw sharpening. This book is profusely illustrated throughout.

From this it will be noticed that the field is well covered, and a book such as this makes an ideal handbook for engineers, factory superintendents, foundrymen, shop foremen, and mechanics in general.

TRAHERN

Rotary Geared Pumps to suit all requirements

Does the cutting tool on your metal working machine require a stream of 1½ or 75 gallons per minute? Whatever may be the need the many styles and sizes of Trahern Rotary Geared Pumps will fill it.

TRAHERN ROTARY GEARED PUMPS

will measure up to the most exacting standards of pump efficiency. The accurate machining and perfect adjustment of TRAHERN pumps render the possibility of clogging or loss of prime a negligible factor. They will work with or without pressure—thus performing the functions of both the rotary and centrifugal types.

Write for our free booklet—it will tell you all about them.

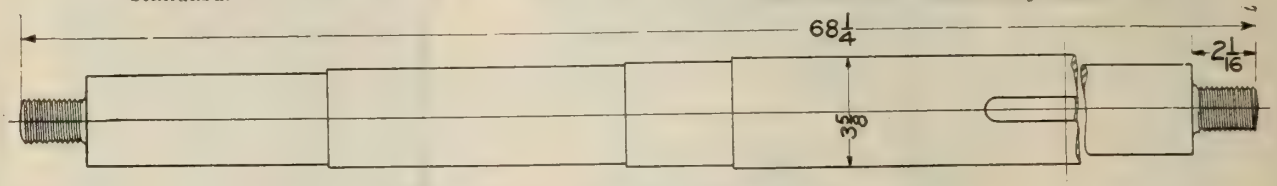
Smalley-General

THREAD MILLING MACHINES

Will give you a short cut to lower-cost thread milling.
Study the blue print and time study as given below.

MACHINE—Smalley-General Thread Miller No. 2.
THREAD—1½ in. diameter, 2 1-16 length, 6 pitch U.S. standard.
PIECE MILLED—Axle for tractor.
MILLING FEED—4.35 per minute.
MATERIAL—Machinery steel.



Tractor Axle Operation
TIME STUDY

5 minutes 37 seconds floor to floor milling both threads. Each thread milled in 65 seconds. Balance of time handling. Barker 3-jaw chuck used which had 12 in. unsupported overhang turn main spindle bearing to thread.

NOTE.—These parts were chucked through the rear end of main spindle. This was an awkward operation because the pieces were larger in the center and the type of chuck would not let them through. A collet chuck with false collets would have permitted faster chucking.

Consult us on every phase of Thread Milling. We will show you how to cut the costs.

Smalley - General Co., Inc., Bay City, Michigan

The Secret of the Strikes

Most Canadians are asking "What is the cause of the 'Great Unrest' "? Is it the fault of labor—or of capital?—or is it the result of German propaganda? Do you know of the real reason for the labor disturbances in Canada, and elsewhere? Are YOU thoroughly familiar with the ins-and-outs of the plans which threaten a world-wide "tie-up?" This is something that should be understood by every Canadian. And every Canadian should read "The Secret of the Strikes," by Lieut.-Colonel J. B. Maclean in the August issue of MacLean's Magazine. It is brimful of startling and authoritative information regarding this great problem. Read it carefully. It starts on page 33, August MacLean's.

"The Lecturer At Large"

Stephen Leacock is one of the continent's greatest humorists. "The Lecturer at Large" is one of the best humorous sketches that he has written. It is made up of what he terms "a few painful reminiscences of the platform" in the course of his lecturing up and down Canada. Get your family around you and read the sketch aloud—it's a rare treat.

Other Big Features

"A Party in the Making." By J. K. Munro. Illustrated by William Casey. An article on the political situation, giving a great deal of inside information with reference to recent developments at Ottawa.

"Solving the Problem of the Arctic." By Vilhjalmur Stefansson. The fifth instalment of his story of the five years' explorations that he conducted for the Dominion of Canada.

"The Unspoiled Country." By Harold C. Lowrey. A descriptive article of a part of Canada which is little known to Canadians generally, Temagami.

"Petite Simunde." By Arthur Beverley Baxter. Illustrated by E. J. Dinsmore. A charming romance of the war. The author will be remembered favorably for his "Mr. Craighouse of New York, Satirist."

"The Seven Blue Doves." By W. A. Fraser. Illustrated by Charles L. Wrenn. The fifth of the Bulldog Carney series and in some respects the best. It is a mystery story.

"His Majesty's Well-Beloved." By Baroness Orczy. Illustrated by C. F. Peters. The second instalment of this splendid romantic novel of the colorful era of Charles II.

The Month's Vital Question

Turn to page 34, August MACLEAN'S, and you will find timely and interesting information regarding the High Cost of Living—a problem of large proportions.

The Review of Reviews

Here are a few of the articles chosen as the best published during the past month in all magazines:—Britain Winning Supremacy of the Air; Has Japan Two Governments?; Kaiser Employed Famous Beauties; The New Triple Alliance; Mammoth Animals in Alberta.

Over 70,000 Canadian Families Buy

A Horizontal Boring Machine

For Heavy Duty or Fine Jig Work

This wide range machine has the strength and rigidity to drive 2-inch high-speed drills to capacity and boring tools up to 8 inches and over, but is so carefully balanced and nicely adjusted as to adapt it equally well to the finest jig work.

Lateral and vertical adjustment of the head to permit the spindle to operate anywhere over a surface 18 by 36 inches; spindle of special forged steel, ground to size, has long nose with 5/8 x 5/8 slot in the end and is provided with ball thrust bearings. Steel gears provide nine different speeds without stopping the machine and the automatic trip guards against the spindle being advanced beyond its intended range of movement.

Six styles of drive: 2, 3 and 4-step cone with back gears, and 5, 4 and 3-inch belt respectively; gear box with tight and loose pulley; variable speed motor, directly connected, and constant speed motor with gear box (as illustrated). Complete description in Circular R-1.

Say you want all particulars.

Dull Files, Dull Workmen

You cannot get the best out of men working with dull tools.

The personal satisfaction they get out of working with sharp, well balanced tools makes for contentment.

It is better to throw away a dull file and buy a new one than to "economize" by keeping the dull file in use.

"Famous Five" Files give maximum returns because the steel in them is accurately cut and properly hardened.

Order them. They are:

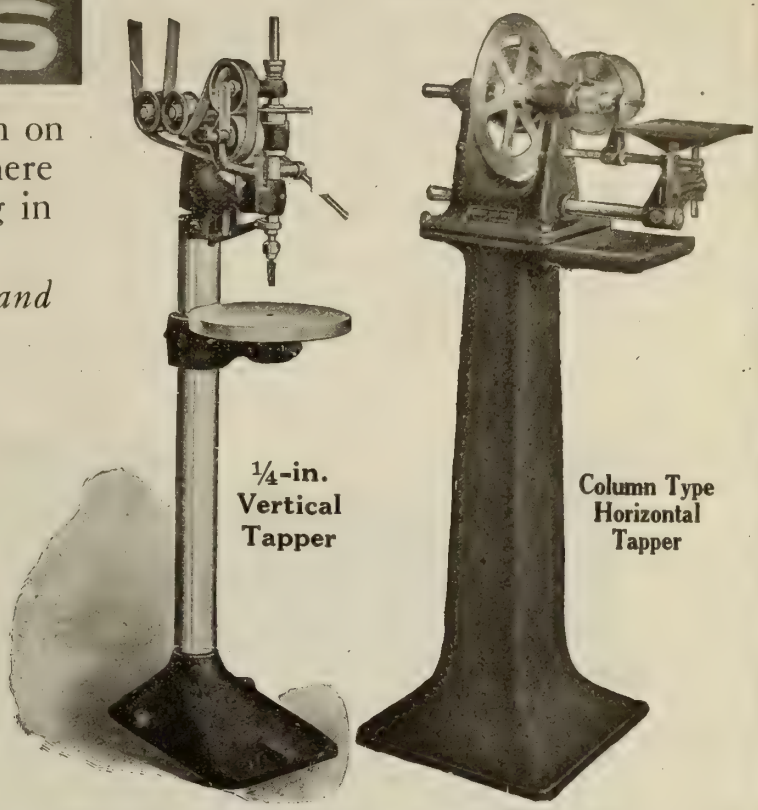
RICKERT-SHAFER TAPPERS

Save Tap Breakage

The *smooth drive* reduces the strain on the taps—they wear longer—and there are fewer delays from taps breaking in the work.

R-S Tappers ensure faster tapping and quicker assembling.

Friction drive, absorbing all the shock, allows a chuck speed of 140 r.p.m. on 5/8-in. work—50 per cent. faster than the usual tapping speed for that size. Uses but 1 h.p.



¼-in. Vertical Tapper

Column Type Horizontal Tapper

FRED HERBERT, Foreign Agent, Coventry, England.

The "Boehm" Positive Opening Threading Die

Hardened and Ground Guides for the Chasers

This Is One Distinct Feature of the

"Boehm"

The "Boehm" Positive Opening Threading Die has a positive opening and closing cam action.

Chasers have the necessary radial movement to enable the die to open after the threading operation has been completed. They are supported by a cam ring throughout their entire length and width. Incidentally—

The chasers slide between hardened and ground guides, and are supported by carriers which have a groove in the outer end for the positive opening cam.

This cam, the locking pins, and the "float" have features that add to the distinctiveness of the "Boehm."

We will be glad to send you complete description.

The Landis 12" x 96" and 12" x 120", Plain

There are many just claims we could make regarding the superiority of Landis Plain Grinding Machines.

We prefer, however, to let you form your own opinion by watching the Landis in operation.

We'll tell where you can see the Landis right in your neighborhood turning out highly efficient, dependable work. The grinding is done by the wheel traveling and the work remaining stationary.

Write us if interested in getting a first-hand impression.

Have you our catalog?

LANDIS TOOL COMPANY, Waynesboro, Pennsylvania, U. S. A.

FOR CONNECTING ROD BEARINGS

A further demonstration of the Excellence of

MAGNOLIA METAL

PERKINS MACHINE & FOUNDRY CO. INC.
FOUNDERS AND MACHINISTS
Amsterdam, N.Y.

May 13, 1919.

Magnolia Metal Co.,
New York City.

Gentlemen:-

The writer has used MAGNOLIA METAL for 18 years with excellent results.

Have used MAGNOLIA on Dynamo and Engine Bearings (Connecting Rods more particularly) and claim it to be the most excellent metal for hardest service obtainable. Am glad, indeed, to be able to recommend it.

Beg to advise that I am a mechanical man of many years experience, having handled all kinds of Babbitts, and MAGNOLIA METAL is my preference.

Yours truly,

PERKINS MACHINE & FOUNDRY CO.,
Augustus H. Morrison,
Engineer and Manager.

RACINE HACK SAW

The merit of a world's record in accuracy and economy stamps this machine as distinctive among metal-cutting machines.

The value of the Racine machine has been demonstrated so thoroughly that we will send you any machine you may select upon approval.

Send for our catalogue and make your choice to suit your requirements.

Stock up to 12" x 12". Motor or belt driven.

We guarantee the accuracy of the Racine.

On the reverse the Racine lifts the blade so that wearing on the cutting edge of the blade is eliminated.

We guarantee to keep every machine we sell supplied with Racine H.S. Tungsten Blades.

One Great Advantage

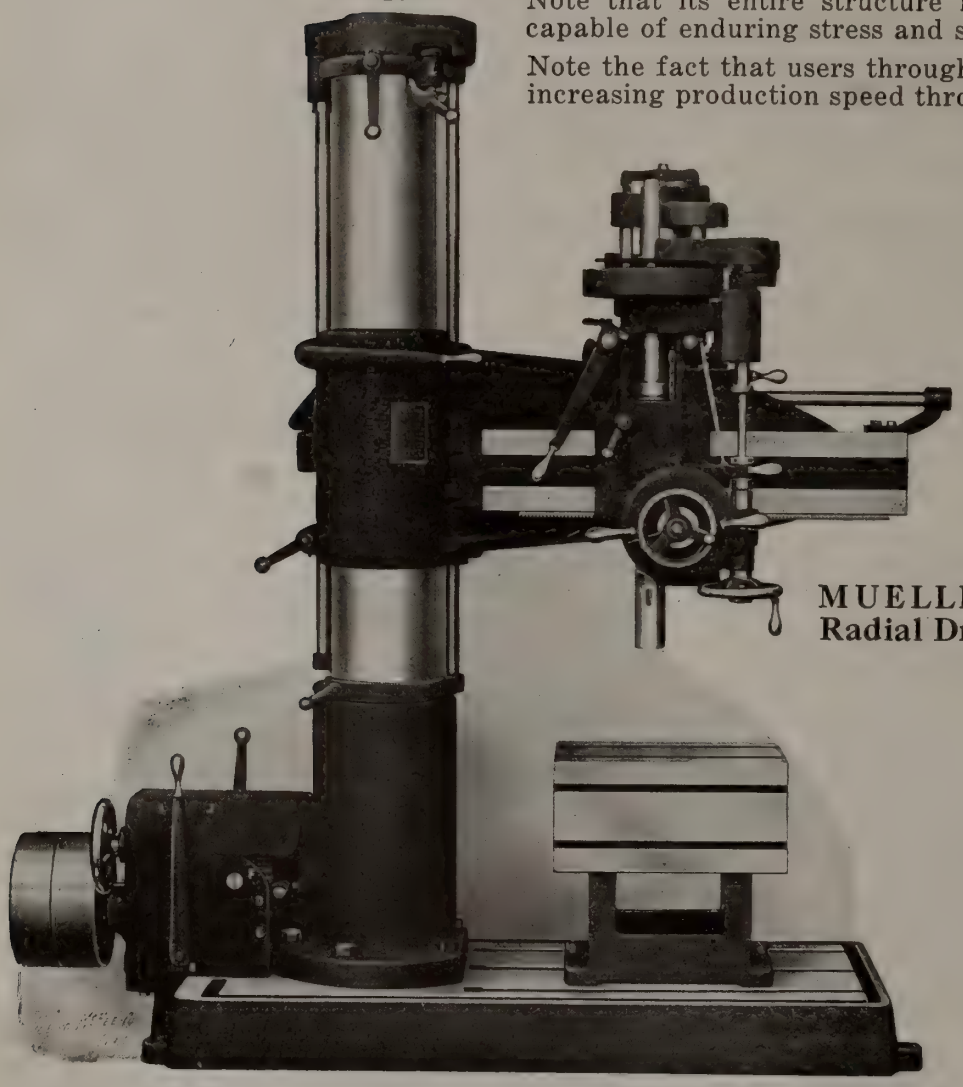
which the Mueller Radial Drill has over other radials is its Patented Stationary Column.

Note its strength—one-piece and stiffened by four internal webs.

Note the fact that every control lever is within easy reach of the operator.

Note that its entire structure is firm, rugged and capable of enduring stress and strain.

Note the fact that users throughout the country are increasing production speed through its use.



MUELLER
Radial Drill

Note the bearing surface of the arm on the column.

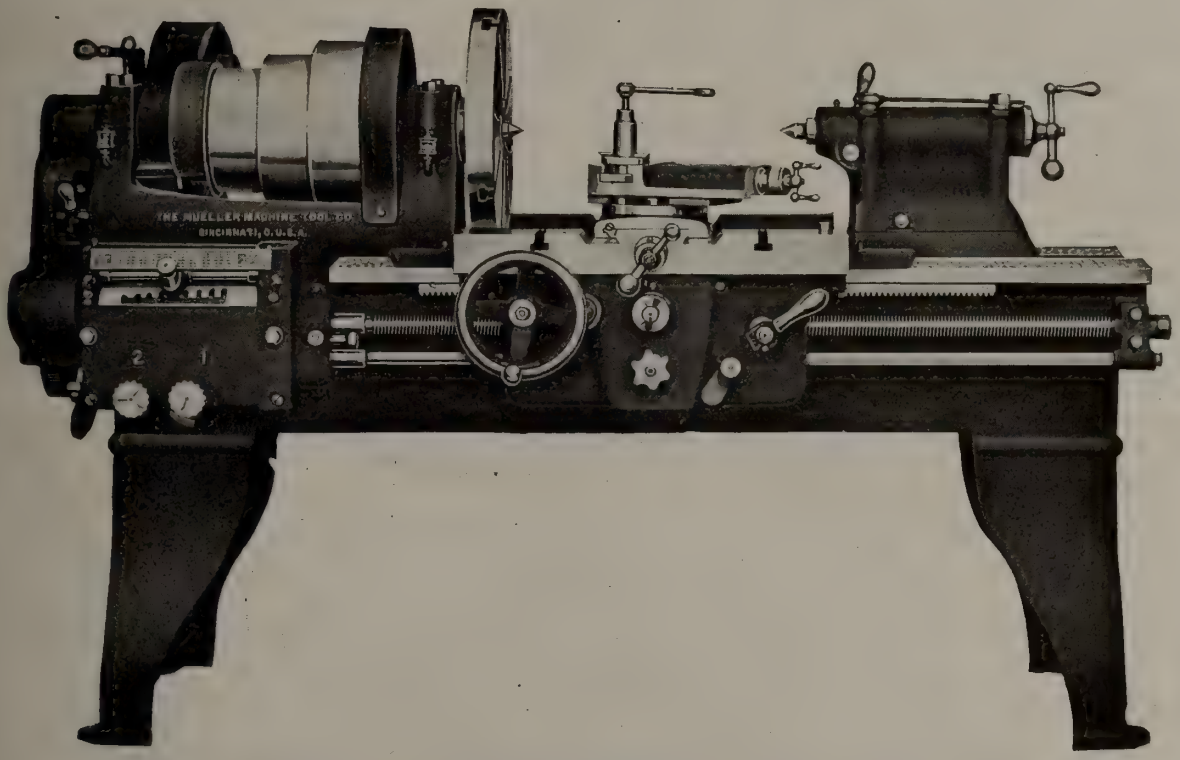
MUELLER HEAVY DUTY ENGINE LATHE



THE headstock is of heavy construction, ribbed and cross-ribbed. The tailstock is very massive in its proportion, with two 7/8-inch bolts for clamping it to the head. It is arranged for two plug clamps, to lock the tailstock without throwing it out of line. The double back gears are of the slip gear type. The spindle is made of high carbon crucible steel, ground to size. Spindle boxes are of phosphor bronze, bored and hand scraped, to fit spindle. The spindle is provided with means for any necessary adjustment. There are eighteen spindle speeds on the machine. Forty-five changes of thread can be cut, ranging from two to sixty, including 11½ pipe thread. All changes are obtained within the quick-change gear box itself. All threads can be cut without the removal or addition of a single gear. The bed is unusually deep and braced its entire length. The carriage is very rigid and capable of withstanding the heaviest strains. Double plate apron is furnished. Steel gears throughout. Sight feed oilers. Automatic stop for carriage.

Write for interesting circular describing machine in detail.

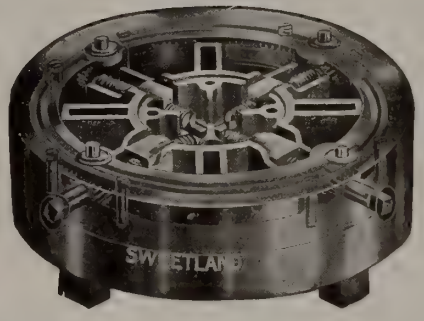
Chucking for Profit

Means the Use of

Sweetland Chucks

as they increase production remarkably by conserving the time and energy of men who operate them.

Note particularly the Sweetland Combination Chuck on the left, for all practical mechanics consider it the best Geared Screw Chuck made. Of simplest possible construction, still complete in its interchangeability from independent to universal operation of the jaws, **or vice versa.**

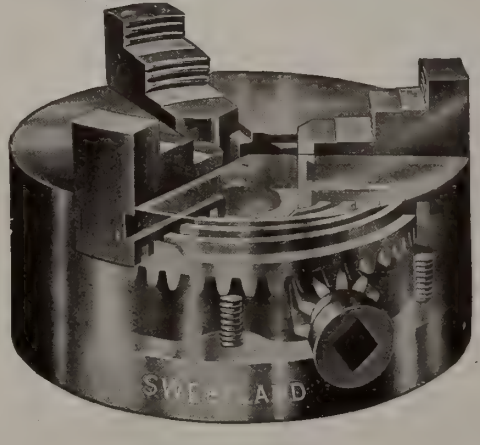


Independent Lathe Chuck

The gripping and gearing surfaces, both of hardened steel, are ground perfectly true. The large screws of special grade steel are flush with the body of this Sweetland Independent Lathe Chuck. The strong jaws are high-grade steel, properly hardened.

Universal Chuck

This Sweetland Chuck has been on the market for over 40 years. Many that long in use are good as ever for accurate chucking work.



Geared Scroll Chuck

Opposite is another Sweetland Chuck, with hardened jaws ground perfectly true on face and bite. Sizes 2½" to 18" dia, both with three and four jaws.

When so ordered this Sweetland Scroll Chuck is supplied with Solid Reversible Jaws—two sets in one; or with Non-Reversible Inside or Outside Jaws, or with both sets.

¼", ⅜", ½", ¾" capacities. Weight from 7 pounds up. Ball and thrust bearings. Gears run in grease. Single and two speeds.

HAND AERIAL GRINDER
For cleaning castings or surface work of any kind. Made in four sizes, ¼ to 2 H.P. Weight from 18 pounds up. Guaranteed for hard usage.

SMITH & MILLS SHAPERS

Permit Changing the Stroke Without Stopping the Machine

No stopping the flow of production with the Smith and Mills. You can change the length of the stroke, whether to shorten or lengthen it, without stopping the machine. You need only loosen locking screw and stop the shaft revolving and the adjustment is made very quickly.

The helical gear on bull wheel eliminates shock. A wrist-pin gear, fitted to the bull gear in an eccentric form, replaces the conventional bevel gear arrangement in the bull wheel. It's an ideal shaper for speed and accuracy. Send for details.

WALLACE Bench Planer

"Speeds Up" Production Cuts Cost

THE bulk—or about 70 per cent.—of your fitting, trimming, jointing or surfacing is on work less than 4 feet long and 4 inches wide. For lack of better facilities you have had to **do** all this work by hand—at an enormous cost. If every operation were as costly you'd close up shop. You can't afford to run to the big stationary jointer with each piece of work —yet that cost must be cut.

THE Wallace Bench Planer was designed especially for small work. It is the quick action machine you need to turn out that bulk of your planing, surfacing, beveling, jointing and fitting efficiently—economically. That's why it's busy in the General Electric, Westinghouse, Reaser Furniture, Long Furniture, Brunswick-Balke-Collender, National Malleable Casting, Pierce-Arrow, Jackson Sash and Door, and hundreds of other shops, from the biggest to the "one man" cabinet, pattern, carpenter shops, etc. In many shops it takes care of **all** the work.

It is portable—works right on the bench—handy at the elbow of your men.

Try this remarkable, simple, cost-saving machine. Stop those daily losses!

The Geo. F. Foss Machinery & Supply Co., Limited
305 St. James Street, Montreal

BECKER
BELT DRIVEN
MILLERS

"THE MACHINE THAT GIVES THE SMOOTH FINISH"

There is no "cut and dried" method with the attendant loss of time to obtain the best feed for the work in hand as is necessary on so-called quick change feed milling machines.

All working parts of the Becker are easily accessible and all changes are made while the cutter is working.

The elastic belt drive of the Becker gives a smooth finish that cannot be obtained with any gear driven machine.

Write for circular 0-705 to-day.

Standard the World Over

"THE RACINE"

HIGH SPEED METAL CUTTING MACHINE

Reduces Blade Expense

Aside from its ability to turn out more work than any other metal cutting machine, "THE RACINE" will save you considerable money on blades alone—enough to pay for itself in a reasonable time. The automatic lifting device is responsible for that. It automatically raises the blade on the return stroke, relieving it of all dragging or strain. This also means quicker cutting, less power used and greater production.

There are many ways "THE RACINE" will prove a big saving. Let us tell them to you.

Use "Racine" H.S. Tungsten Power Blades

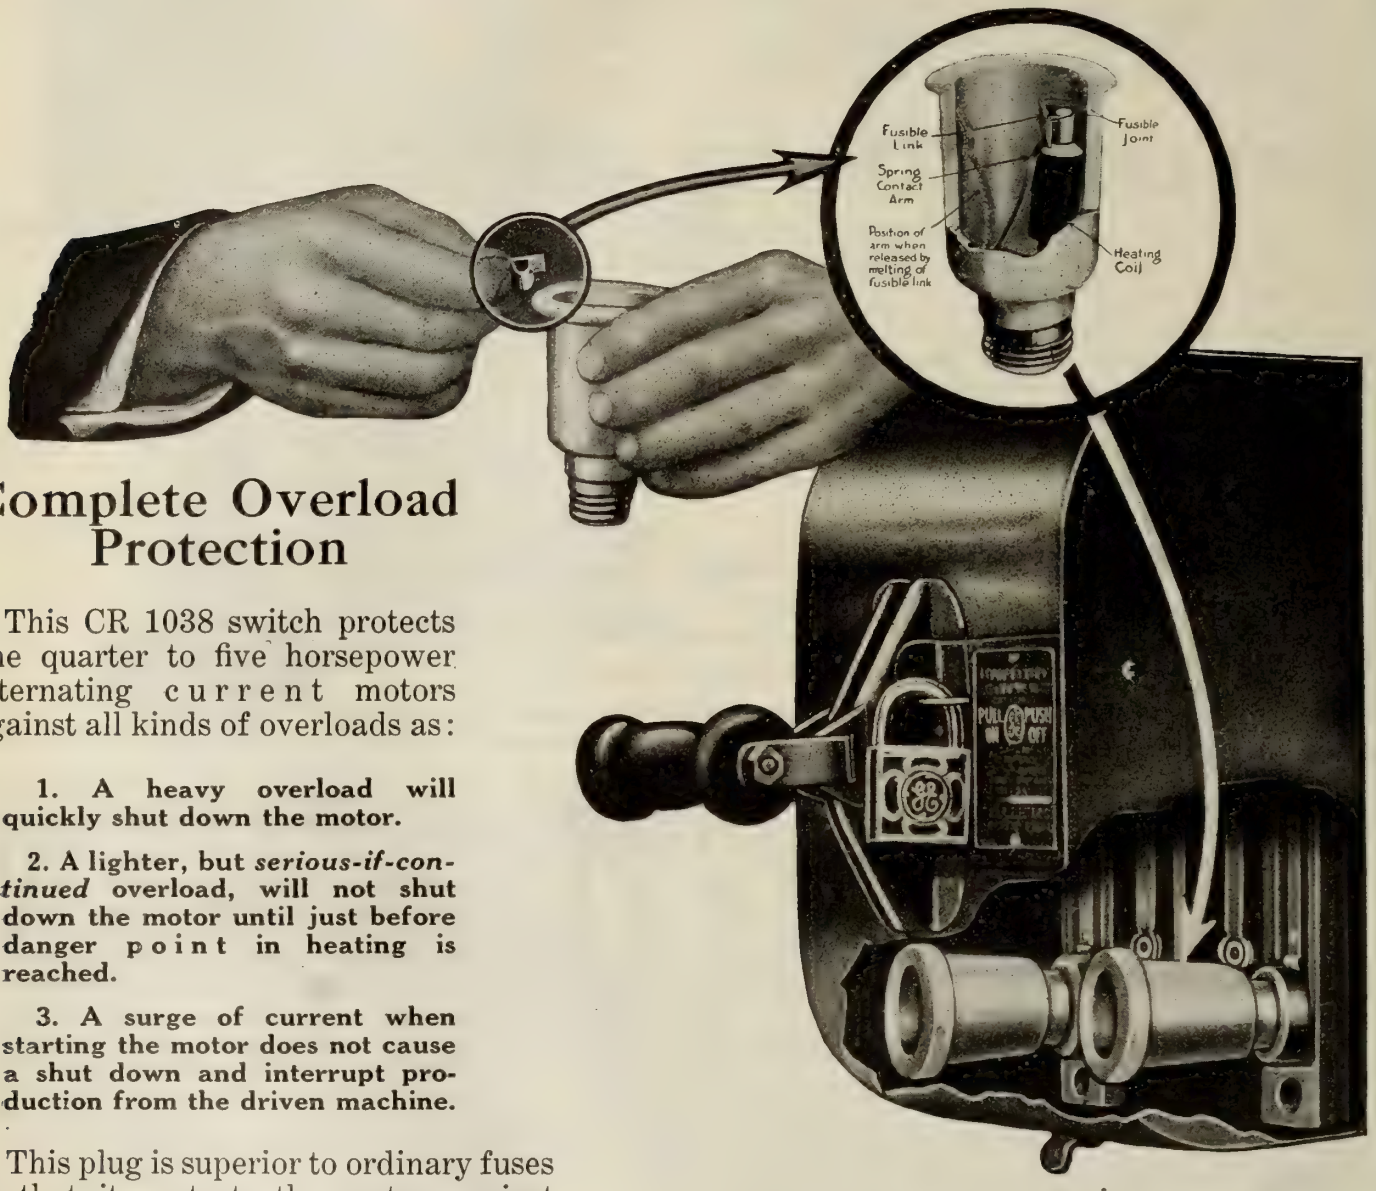
MacKINNON STEEL CO., LIMITED

Sherbrooke, Quebec

Montreal Office: 404 New Birks Building

Important motor driven productive machinery must be kept going. Interruptions are practically eliminated where motors are automatically protected against only the overloads that injure.



Complete Overload Protection

This CR 1038 switch protects one quarter to five horsepower alternating current motors against all kinds of overloads as:

1. A heavy overload will quickly shut down the motor.

2. A lighter, but *serious-if-continued* overload, will not shut down the motor until just before danger point in heating is reached.

3. A surge of current when starting the motor does not cause a shut down and interrupt production from the driven machine.

This plug is superior to ordinary fuses in that it protects the motor against overloads, which are serious because continued, while the former protected only against peak overloads.

Ask our nearest office for descriptive sheet No. 68327A.

A small spring switch in the porcelain protective plug shown is held shut by slipping a little link over its end. If a current large enough to injure the motor flows through the plug the fusible joint of the link is melted by the heating coil. For the cost of a postage stamp the link can be renewed and plug made operative again.

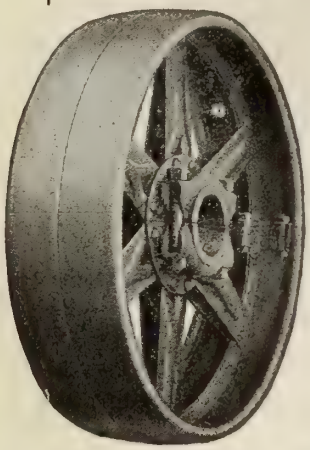
AMERICAN STEEL SPLIT PULLEYS



Correctly designed for maximum strength and light weight. Save power and save coal. Guaranteed for minimum belt slip, minimum air resistance, double belt service and recommended for rim speeds up to 6,000 feet per minute. Easy to install—no keyway or set screw needed. National distribution through supply houses from parent stocks in larger cities.

Write for 37 page booklet, "Getting Maximum Pulley Efficiency." Free on request.

THE AMERICAN PULLEY COMPANY

Philadelphia, Pa.

"SPIRO" COMPRESSION COUPLINGS

The Joint is as Strong As the Rest of the Shaft

Are you installing new shafting? Do you wish to lengthen your present shafting? Never mind if your stock isn't long enough. Remember a "Spiro" joint will stand the same torsional strains as the rest of the shafting.

When the two shells "B" and "C" are brought together by the tightening of the bolts the sleeve "A" with its spiral slot just "wraps itself around" the shaft with such strength that it's safe to list the whole outfit ever afterwards as one piece.

You save its cost through installation charges being reduced and elimination of keys and key-seating.

We keep all standard sizes in stock. It pays for itself. Why not order it now.

Canadian Machinery BUYERS DIRECTORY

If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

MORSE TWIST DRILL & MACHINE CO.
NEW BEDFORD MASS., U. S. A.

NEW Cleveland POCKET-IN-HEAD Riveter

NEW CLEVELAND "POCKET-IN-HEAD" RIVETING HAMMER MOST POWERFUL RIVETING HAMMER ON THE MARKET

NEW Cleveland POCKET-IN-HEAD Riveter

The New Cleveland is shorter over all. Hits a harder blow, and uses less air than any hammer made.

The New Cleveland has a higher speed with less recoil in operation than any riveter on the market.

We can prove it in your shop

THE NEW CLEVELAND is made in 15 sizes with Outside or Inside Latch, and is adapted to all classes of work upon which Riveting Hammers can be used.

THE NEW CLEVELAND has a driving range in rivets from ¼-inch to 1½-inches, and is especially adapted for heavy riveting in Boiler or Structural Work.

IN STOCK: Riveting Hammers, Chipping Hammers, Air Drills for Reaming and Tapping, Breast Drills, Sand Rammers—Floor and Bench, Corner Drills, Portable Air Grinders, Bowes Air Hose Couplings, etc.

Write for Bulletins 34A, 41 and 43

Bowes Air Hose Couplings

Standard Equipment Everywhere.

Air tight under all pressures. Quickly connected or disconnected.

Interchangeable in all sizes from ¼-inch to ¾-inch inclusive.

Shows Cleco Never-Slip Hose Clamps Attached to Bowes Couplings

"THE MAPLE LEAF" FOR EVER

Economy, Durability, Efficiency and True Running

We are the sole manufacturers of the celebrated

"Maple Leaf" Brand Stitched Cotton Duck Belting

"Maple Leaf" Belt Dressing

The best on the market for **Transmission of Power, Conveying, etc.** Also **"Maple Leaf" Belt Dressing,** which is unexcelled, and equally good for using on all kinds of belting.

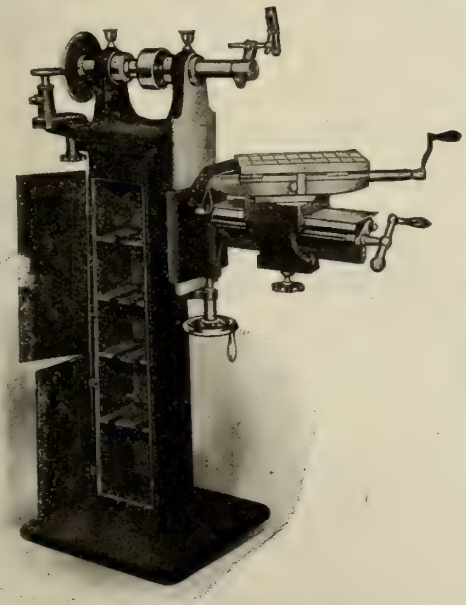
Write us for prices.

DOMINION BELTING CO., LIMITED

HAMILTON - CANADA

Quebec Branch: 51 Duluth Building, Montreal

OBTAIN THE BEST RESULTS



GARVIN No. 3, Universal Cutter and Surface Grinder
Use Code—Banish

From Cutters and Tools Kept Sharp on

GARVIN No. 3 UNIVERSAL
CUTTER AND SURFACE GRINDERS

Simple Light Running Accurate

The spindle is hardened and ground and supported out close to the wheel by an extended bearing, and carefully protected from emery.

The knee and the yoke carried on the knee both have a large range of adjustment. On the knee yoke or carriage is mounted the swiveling table, which has a quick, sensitive movement by rack and pinion operated from end or side.

On this table is mounted the index head, and all the attachments are held in this head.

An outfit of emery wheels, mandrels, bushings, wrenches, etc., is supplied with the machine.

Machine is designed to keep its original factory accuracy.

CAPACITY: CUTTERS, 14" x 6"; SURFACES, 9½" x 5"

An Opportunity and a Guaranty

W&B
Trade Mark

Here is a life insurance policy on Twist Drills, Reamers and Screw and Drop Forged Wrenches, Steel-stamped into every tool we make, this trade mark is a safe and sure guaranty of successful and economical performance.

THE "W & B" Trade Mark is our signature on the tools we make. It makes good. Before it is stamped on a Twist Drill or Reamer, we have made sure that the tool is up to our standard, and our standard is the highest in the world.

Buying "W & B" Twist Drills and Reamers is an opportunity open to all who want the most for their money. The "W & B" Trade Mark is our guaranty that you get the most for the money.

There is no question in any efficient shop about the goodness of "W & B" tools. The best things ever said about "W & B" Twist Drills and Reamers have been said by those who use them.

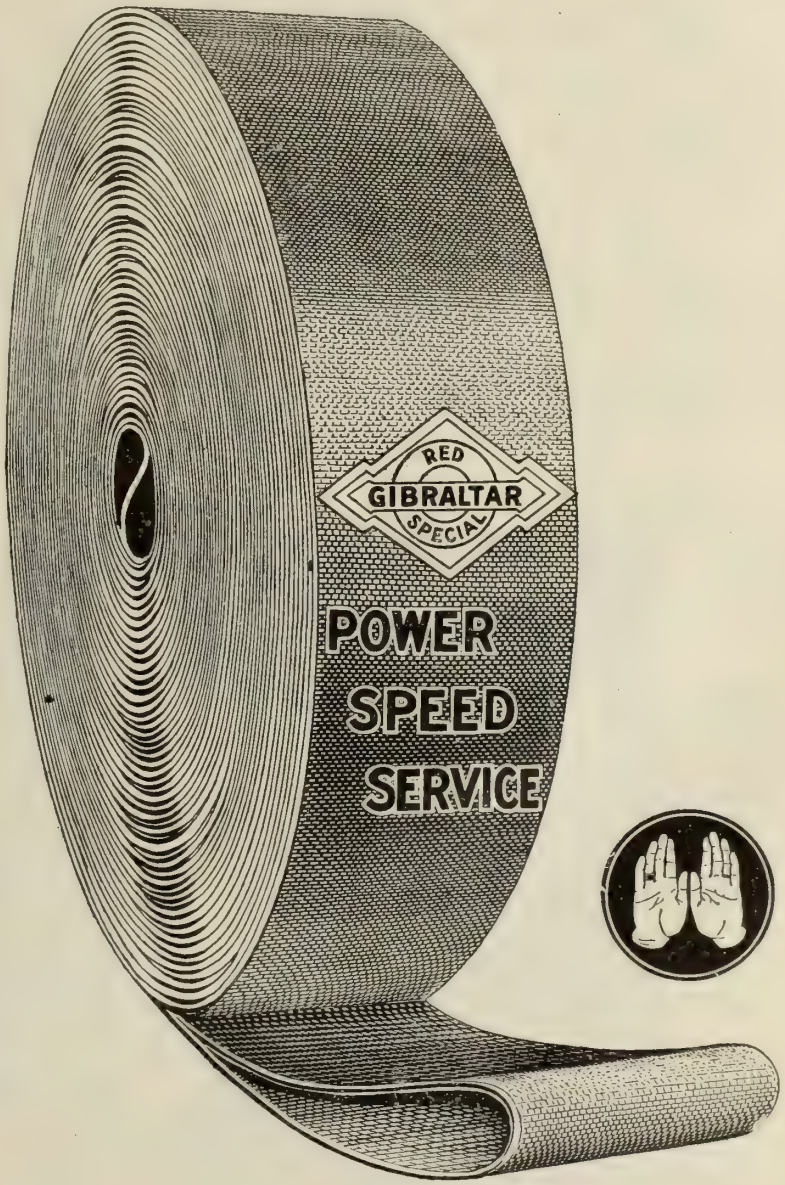
"Gibraltar RedSpecial" Belting

"THE ORIGINAL RED FRICTIONED-SURFACE RUBBER BELTING"



WHEN it's a question of unusual achievements in Beltdom, "Gibraltar RedSpecial" stands supreme.

As an effective means of trimming down "overhead" it is known far and wide.

This Red Frictioned-Surface Belt has dominated the field since its inception.

Without variation this belt has lived up to the exacting standard of service set by us when it was first introduced to belt buyers.

Having been tested and tried to the limit in all manner of places—and by thousands of users throughout the country from the Atlantic to the Pacific—"Gibraltar RedSpecial" will also secure you against the uncertainties which surround the use of "just-as-good" brands.

The price may be higher than that of "ordinary" belts, but the service is long and satisfactory in the extreme, as a multitude of long-time users will gladly testify.

With the Dunlop Unreserved Guarantee which goes with every belt, you should have no hesitation in making your next order read "Gibraltar RedSpecial."

You know the Dunlop reputation for square-dealing, too.

Dunlop Tire & Rubber Goods Co., Limited

Tractor Gears and the Gear Shaper

Refinements in tractor transmissions have been brought about as a necessary development of the tractor as a whole. Alloy steel forged gears have taken the place of steel castings and other inferior materials for high-duty work.

This refinement in good tractors has been carried on all along down the line through the processes of manufacture. There is little advantage to be gained in using high-grade materials for gears unless the gears themselves are accurately cut.

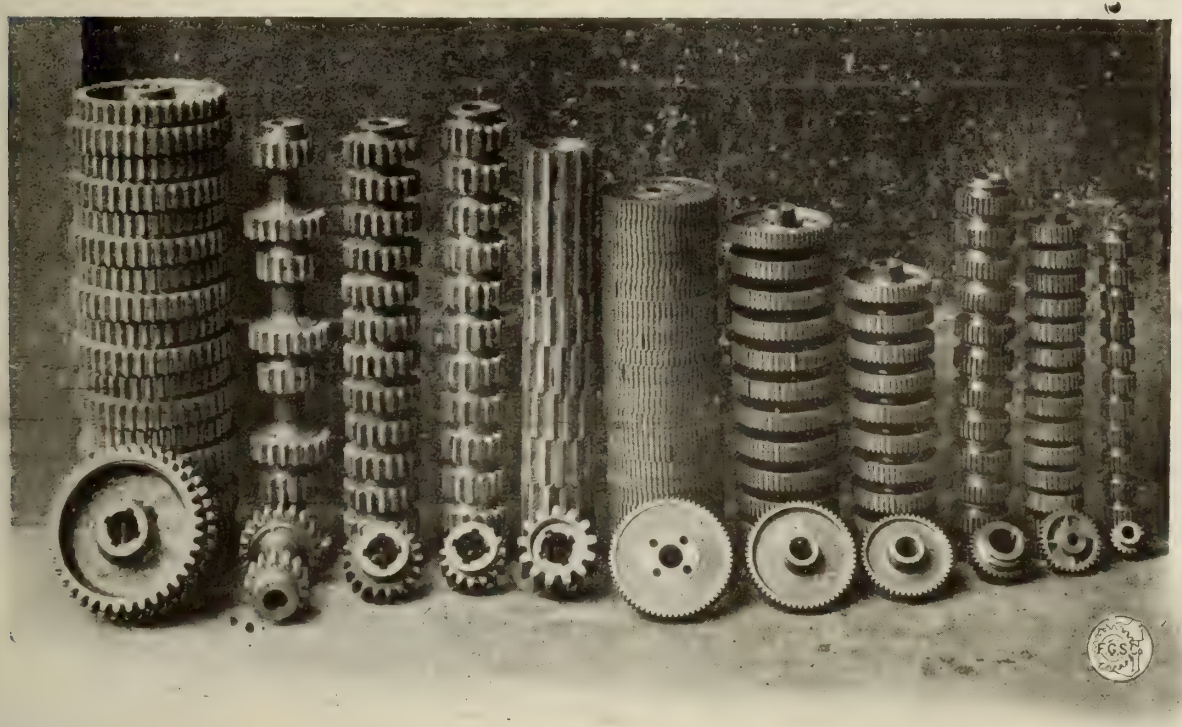
It is for this reason that tractor manufacturers and makers of tractor transmissions are using the Gear Shaper for finishing all of the spur and helical gears entering into the power transmission units of their tractors.

Another reason, which from the cost end is a highly important one, is that tractor gears can be more economically produced on the Gear Shaper than by any other process. Hence, the Gear Shaper combines both accuracy and production.

Among the manufacturers of tractors that are using the Gear Shaper is the Emerson-Brantingham Co., Minneapolis, Minn. We show herewith a collection of gears used in Emerson-Brantingham tractors that are finished on the Gear Shaper.

The Gear Shaper has played no small part in the production of efficient transmissions for automobile and truck use, and is now filling the same position in the tractor field.

Tractor manufacturers desiring assistance in connection with their gear problems are cordially invited to take up such problems with our Engineering Department. This service is given gratis. We will also send a copy of our book "The Internal Gear" to those interested in internal gear design.



Collection of Emerson - Brantingham Tractor Gears Generated on the Fellows Gear Shaper.

The Fellows Gear Shaper Company

IMPERIAL CARBIDE

For Welding Cutting and Lighting

HIGHEST GAS YIELD
IMPERIAL CARBIDE
MADE IN CANADA

It insures **effectiveness** and **economy** by **invariably** producing acetylene gas of **unusual purity.**

Manufactured by

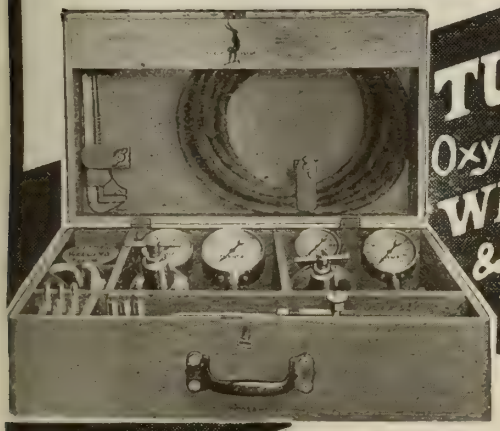
Union Carbide Co. of Canada, Ltd.

Head Office:
Dominion Bank Bldg.
TORONTO, ONT.

Works:
WELLAND
ONT.

Large Stocks maintained at convenient distributing centres throughout Canada

For Repairing Broken Machinery or Tools of Medium Size



These outfits will soon pay their cost in machine parts or tools reclaimed. The sectional extensions of the torch enable the operator to adjust it to any desired length or angle. The location of valves is such that the flame is controlled by one hand, leaving the other hand free for the work at all times.

SYCAMORE, ILLINOIS, U.S.A.

Oxy-Acetylene Welding and Cutting

Welding all seams, flanges, and nipples by Prest-O-Lite Process at a great saving in cost.

Leak-Proof Tanks Cost Less to Make

This illustration shows one of a series of welded tanks, used by a large manufacturing company to contain a searching chemical liquid. Conclusive tests proved the tanks positively leak-proof. They cost much less to make by welding than by any other method.

In thousands of shops and factories the Prest-O-Lite Process of oxy-acetylene welding is displacing the rivet, bolt and threaded joint. The result is neater, stronger work and reduced cost.

For routine construction work, or "on-the-spot" repairing the Prest-O-Lite Process is unequalled.

Prest-O-Lite PROCESS

employs both gases (acetylene and oxygen) in portable cylinders. Prest-O-Lite service, which insures prompt exchange of full cylinders for empty ones. Provides dry, purified gas, insuring better welds, quicker work and lower operating cost.

Apparatus consists of an equal pressure blow-pipe, automatic regulators and gauges, and all necessary equipment. Adaptable for oxy-acetylene cutting by the addition of special cutting blow-pipe.

Thorough instructions are furnished free to every user of Prest-O-Lite Dissolved Acetylene. Any average workman who understands metals can learn the welding process quickly and easily.

We will gladly send illustrated literature and interesting data showing actual instances of savings made by others. It may suggest valuable ideas to you. Write for it.

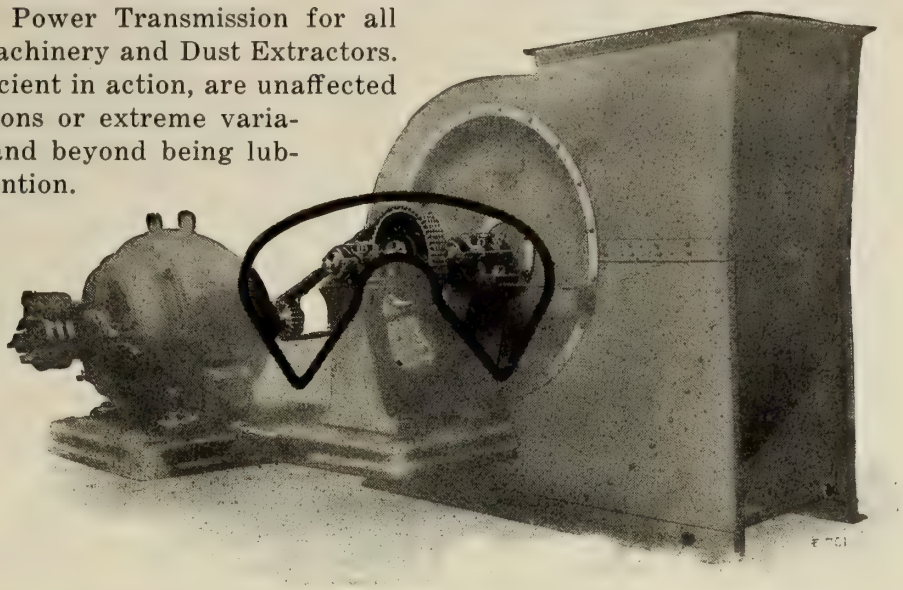
"The Coventry" Noiseless Chains

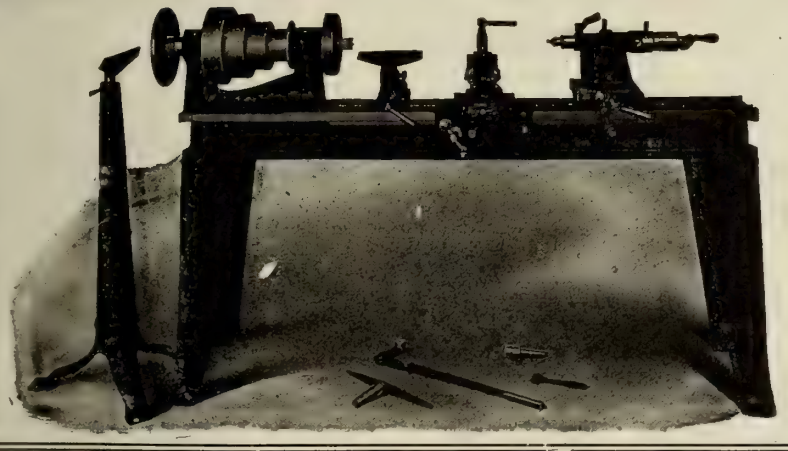
are the ideal form of Power Transmission for all kinds of Ventilating Machinery and Dust Extractors. They are silent and efficient in action, are unaffected by atmospheric conditions or extreme variations of temperature, and beyond being lubricated, require no attention.



A 25" Keith fan, driven by "The Coventry" Noiseless Chain Motor of 7½ h.p., running at 950 r.p.m., fan 400 r.p.m. This illustration shows how floor space is saved by using chain transmission.

"The Coventry" Chain Company, Ltd., Coventry, England

CANADIAN AGENTS--TAYLOR & ARNOLD, LIMITED, Bank of Toronto Building, MONTREAL



A Favorite—

Blount Pattern-makers' Lathe

FAST AND ACCURATE—Equipped with set over swivel tailstock and carriage, and outside face plate and tripod. Built in 16" swing with beds 6 or 8 feet in length. Spindle is made of high carbon steel, is hollow and fitted with Morse Taper and runs on self-oiling bronze bearings.

Our catalog gives a full description of this strong and highly efficient machine, also our other quality speed lathes and grinders. Give us your address.

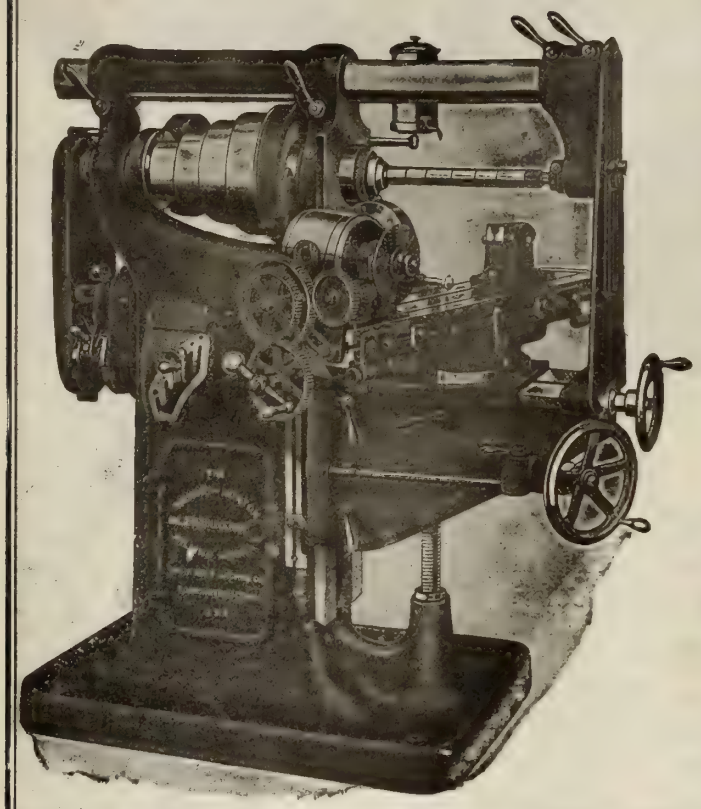
Anybody Can Operate This Miller



and Turn Out a Pile of Work so Simple to Operate is the

"HENDEY"

Skilled mechanics are scarce these days—but anyone can run a machine of its simplicity and turn out work accurately and fast without trouble.

All Feeds positive driven through gearings giving 18 changes.

This is the universal type—designed to handle all milling operations performed on machines of this character, either with regular equipment or by aid of attachments, which can be supplied for increasing efficiency and scope of machine.

CANADIAN MACHINERY AND MANUFACTURING NEWS

A weekly newspaper covering in a practical manner the mechanical power, foundry and allied fields.
Published by the MacLean Publishing Company, Limited, Toronto, Canada

Vol. XXII. No. 6 Publication Office: Toronto, August 7, 1919 Subscription Price $3.00 per year.

Individuality

A GREAT MAN wrote this: "I'm called away by particular business, but I leave my character behind me." And nobody had to guess whose character it was. Even if the familiar Red Cut label should disappear there would be no doubt as to the character of the steel that remained. More than ever would the quality shine forth in the results when it was worked. Adherence to the highest standard with an unvarying uniformity has placed a well merited reputation all its own on

PROMPT SERVICE

is assured at our nearest store where P. & W. Small Tools are carried in stock. Place your order there to-day.

and get the right combination at once.

HOLDER, CUTTER and GUIDE

With this combination you can immediately make the right combination for every counterboring job.

HOLDERS

End of holder is milled to receive the driving lug of the cutter, and there is also a hole and set screw to accommodate the shank of the guides.

GUIDES

Are of hardened tool steel. They are held in place by means of a set screw in the holder engaging a V-slot in the shank of the guide.

CUTTERS

Can be furnished of either carbon or high-speed steel.

The shank of the guide passes through the hole in the cutter and the shoulder between the guide and its shank keeps the cutter in place. Cutters can be sharpened on the face, and the guide is simply pushed further in the hole after grinding.

Holders, Cutters and Guides are furnished in a wide range of sizes.

Purchase the Products of Canadian Mills

TO uphold the Glory we have jointly earned—to honor our noble dead—to comfort the wounded, and extend to the men returned the hand of prosperous welcome, we must cast aside all forebodings and face the future with unbounded courage and confidence and, without a shadow of doubt, declare to the World that this Nation, which was so quickly and successfully transformed to a War basis, can be depended upon to revert to Peace conditions with equal success. The buyer and seller must recognize their duty to the Nation and co-operate fully to the end that all products that can be produced in Canada by Canadian workmen shall not be purchased elsewhere.

OUR Duty is plain; Canada with Canadian labor and capital can produce, manufacture and distribute products sufficient to keep the wheels of industry turning to the limit. The song of Prosperity and Happiness should ring out all over the land. Let us sincerely pledge to the extent of our needs, to purchase materials produced in Canada by Canadian Workmen, and the result of our efforts will return to us the Blessings of a Prosperous and Happy Nation.

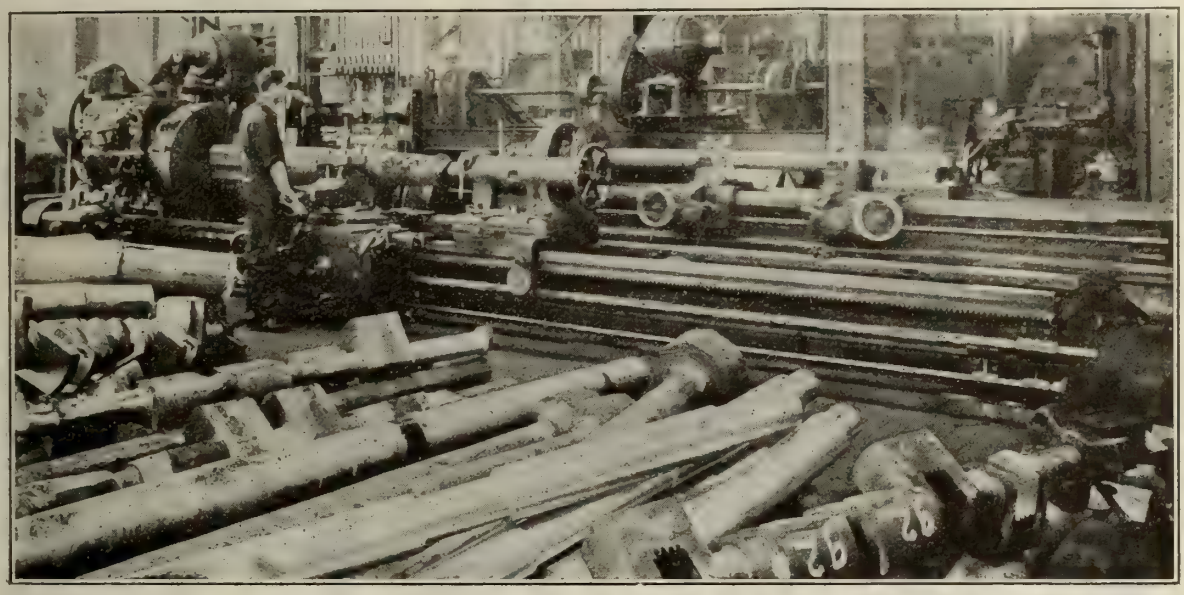
BRIDGEFORD

Heavy Duty Lathes



The above photograph shows a Bridgeford 27″ Manufacturing Lathe finish boring a cast-iron transmission housing for the new Fordson Tractor.

The diameter of housing is 19⅛″ and the limits of accuracy are .002″.

Maximum production is a requirement in the Ford plant and that is why a Bridgeford was selected to do the work. The Bridgeford turns out 80 pieces per day of 8 hours, which is excellent production.

There's a Bridgeford for every heavy duty lathe requirement. Bridgefords are in operation in all parts of the world on all kinds of duty. The line includes Heavy Geared Head Engine Lathes from 24″ to 72″ swing, Cone Driven Engine Lathes, Axle and Journal Truing Lathes and Manufacturing Lathes of 27″ and 30″ Swing.

Send for interesting data on Bridgeford Lathes.
We are in a position to make prompt deliveries.

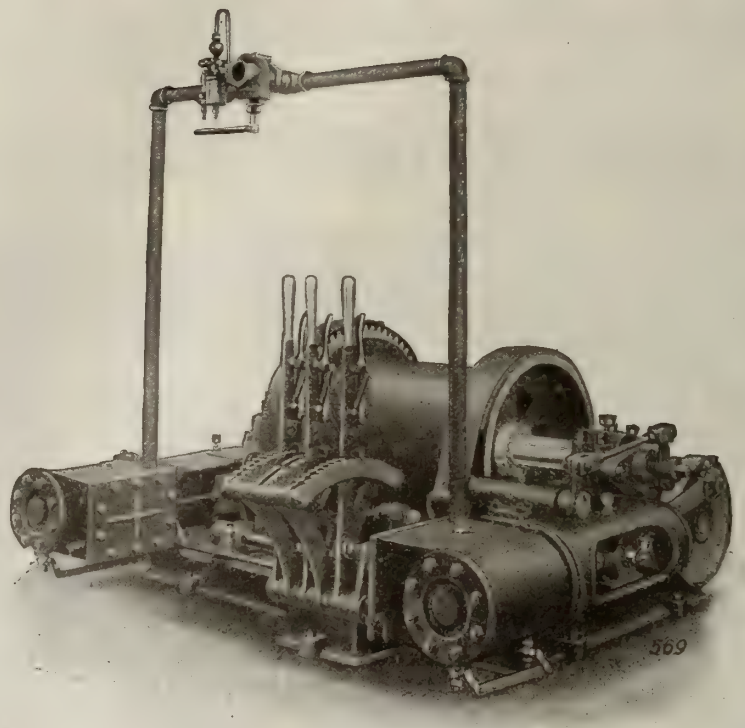
BRIDGEFORD MACHINE TOOL WORKS

161 Winton Road, Rochester, N.Y.

Manufacturers of Heavy Duty Lathes for more than 20 years.

BRIDGEFORD

THE "CIRCO" MINE HOIST



"CIRCO" Mine Hoists have many excellent features of design which are not usually found in machines of this class. The cylinders are cast separately from the frames, and are interchangeable, thus permitting one spare cylinder to be used on either side, and doing away with the necessity of buying a new frame, should one of the cylinders be accidentally damaged. The crosshead guides are bored and the end of the frame faced at the same setting, insuring accuracy and permanency in alignment. A raised ledge around the crosshead guides prevents oil from dripping, which is a common fault in the ordinary mine hoist.

The exhaust may be connected to either the top or bottom of the valve chest as may be most convenient. The drum shaft bearings are bolted to the frame instead of being cast in one piece as heretofore, and are easily replaced if necessary. The eccentrics are of the locomotive type, and the drum gear and pinion are made of Semi-Steel.

Prompt delivery can be made of "CIRCO" Mine Hoists in sizes of from 6 x 8″ to 10 x 12″, with lifting capacities of from 4,000 to 10,000 pounds, and larger sizes will be supplied on special order.

Our nearest branch will be glad to submit complete specifications of these high grade Made-In-Canada Hoists on application.

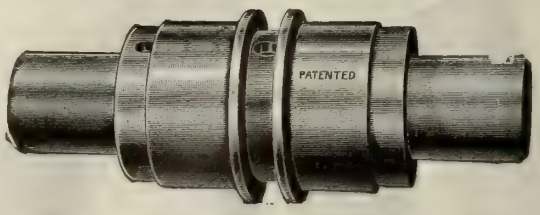
THE JOHNSON FRICTION CLUTCH

BUILT FOR LONG SERVICE



It takes time to do anything well, but the results usually justify the effort. Johnson clutches represent years of practice on one particular line. Our long experience in studying the demands of the trade, in refining our methods, in recording performances, and in selecting materials—all this is reflected in the present quality of our product.

Our engineers are at your disposal to help you with your clutch problems. Just send them your blue prints and they will do the rest. The Johnson clutch which they install will be correctly designed, properly rated, and honestly built. It will give that long and continuous service for which it is famous, and in which alone lies satisfaction.

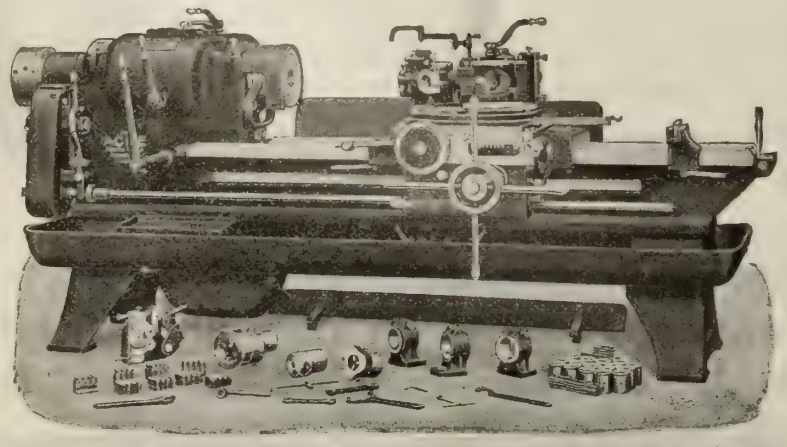
Doubly Efficient—Does Both Bar and Chuck Work

This Cincinnati Acme Flat Turret Lathe is a double-production, geared head machine of the sliding gear type. It operates on minimum power because the only gears running are those doing the actual work.

This machine saves remarkable time and labor machining either bar work or chuck work up to 16 in. diameter.



3¼ in. x 36 in. Flat Turret Lathe, Equipped for Bar Work.

Head is cast solid with the bed. You know what that means: accuracy, rigidity, constant and perfect alignment of spindle with vees, upon which the turret carriage travels.

We also make a full line of Screw Machines and Turret Lathes.

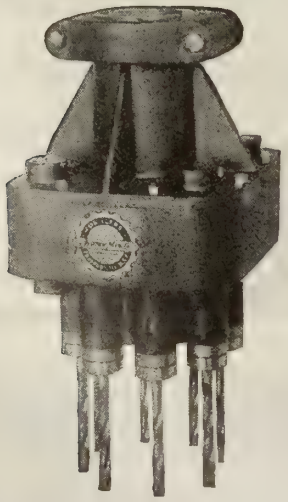
2 Minutes or 20?



This Is The Vital Question

Do you drill ten holes in the time it takes for one? The Hoefer Auxiliary Head equips any driller so as to accomplish this big saving in time. It speeds up production in drilling tremendously. Not only do you save the drilling time, but also the time now lost in shifting the jigs and raising and lowering the spindle for the extra holes.

Hoefer Auxiliary Heads are made in any multiple, arranged in any manner, from 2 up. They are made by expert tool makers and unqualifiedly guaranteed to handle accurately the work for which they are designed.

Investigate now—every day you use a single drill where the multiple may be used you are paying for an auxiliary head through increased costs, but not securing its benefits.

Write for catalog. Send a blueprint of some of your work for estimate of time cost.

ELECTRITE

High Speed Steel

SEVERAL factors combine to make this high-speed steel a triumph of the steel-maker's art; Electric Furnaces — entirely infallible, automatically regulated, delivering the same result time after time.

Uranium — This rare element, cousin to Radium, effects a profound change in the texture and quality of the steel.

Added to these, the constant care and skill of years of steel-making experience make the result of each melt a foregone conclusion.

FRANKLIN DIE-CASTINGS

The Possible Manufacturing Economies

GO over your product again. There may be some simple little part, or a complicated one, which would serve its purpose as well, or better, if produced by our die-casting process. If so, you will economize in manufacturing costs. And if we undertake the job the efficiency of your product will not suffer because it is not only our business to produce die-castings but to see that they are not wrongly applied.

Let us put our 27 years' die-casting experience on your *possible manufacturing economies.* Special attention given to Canadian manufacturing requirements for fuller development.

We are equipped to cast in aluminum, lead, tin and zinc base alloys.

Send sample or blueprint for recommendation and estimate. Ask for Booklet "C."

Franklin Manufacturing Co., 746 Gifford St., Syracuse, New York, U.S.A.

8	Threads per inch R. H.	12
1 in.	Length of Gauge	1⅛

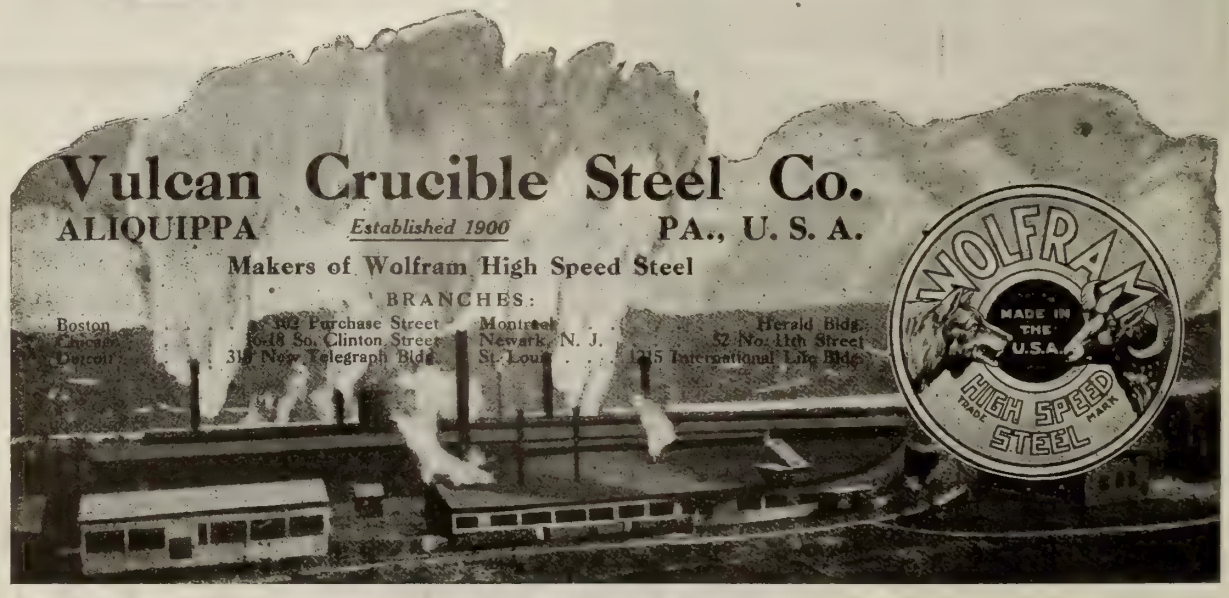
TOLERANCES

Pitch Diameter—Plus or minus .0002
Lead—Plus or minus .00025 per inch of length
Angle—Plus or minus 5 minutes

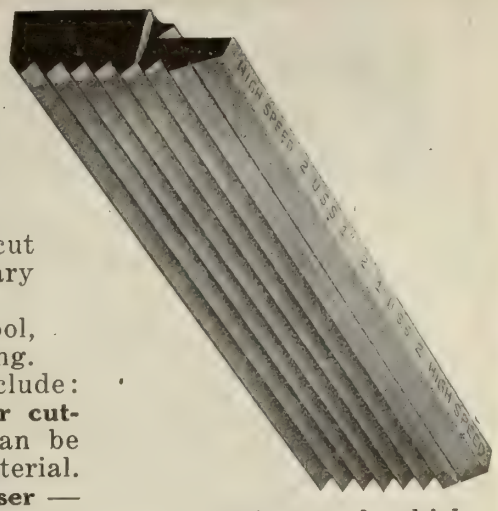
Allowance on pitch diameter for grinding .003 to .005, depending on diameter of gauge.

Change in Hardening { Lead not over plus or minus .001 per inch of length. Diameter not over plus or minus .001 per inch of diameter.

Name of manufacturer of gauges furnished on request.



The Chaser is the Factor in Threading



Any die will cut a thread—that is its purpose; but to cut threads profitably and threads that are better than ordinary requires a **different chaser.**

The Landis Die, embodying the characteristics of a lathe tool, gives you those features necessary for successful threading. These features include:

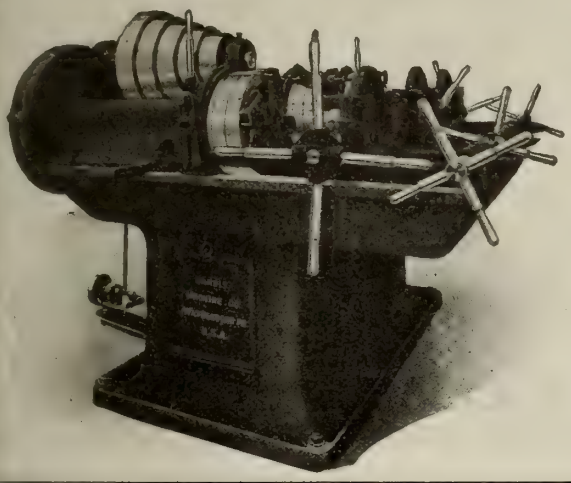
Variable rake or cutting angle which can be ground to suit material.

Long life of chaser — you have three inches of available cutting stock which gives a life twenty times that of other dies.

No annealing, hobbing and retempering—just grind the chaser on the end and you have a new die.

Interchangeability—any one of a set of chasers can be replaced without renewing the entire die.

Tangential disposition—chaser has a line contact with the stock, reducing the friction to a minimum and doubling cutting speeds.



Why not investigate this die and learn just what it can do to your threading requirements? Catalogue No. 24 will give you details.

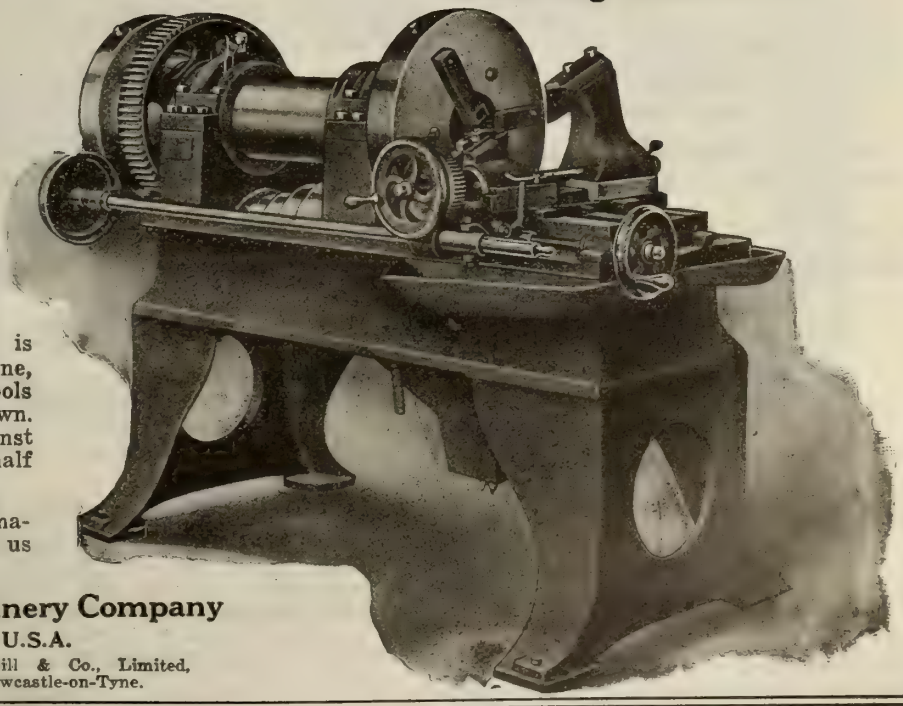
Cut Your Cutting-off Costs in HALF

HURLBUT'S

Patent Cutting-off and Centering Machines

TO say that the Hurlbut, Rogers Cutting-Off and Centering Machine will **double your production** and **cut your costs in half** may seem like a broad claim. But this is just what this machine will do compared with any ordinary machine of its kind.



Hurlbut, Rogers speed and efficiency is easily explained. Instead of only one, it is equipped with two cutting-off tools —one cutting up and the other down. In this way they hold the work against each other and finish a job in just half the time and do twice the work.

You can't afford to be without this machine. It saves real money. Let us tell you more about it. Write!

A WALL RADIAL DRILL

That Puts Dollars in Your Pockets

Here's a real machine tool in the wall radial drilling line for your consideration. Listen to this—the machine is made of high grade materials throughout, and the workmanship is beyond criticism. It is designed with the particular idea of maximum production, at a minimum operating expense. Entire control within easy reach makes the operators "boosters" for these machines. You can keep the dollars that may be slipping away on your wall radial drilling propositions, in your pocket by the installation of this machine.

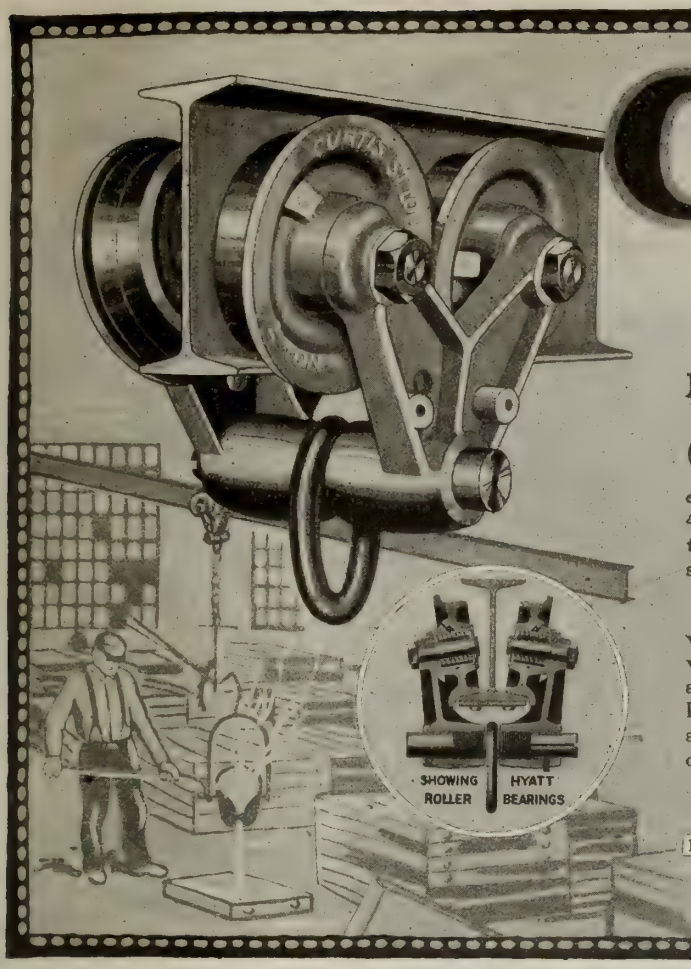
Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25%; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood pattern-makers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.
We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us.

ASK US



CURTIS TROLLEYS

Increase Production—Save Man-Power

CURTIS Single I-Beam Trolleys are being used by progressive firms demanding the highest operative efficiency. A Curtis Hyatt Roller-Bearing Trolley with a 4000-lb. load can be moved by a 50-lb. pull, while ordinary trolleys require nearly twice as much power to move the same weight.

Curtis Trolleys are constructed with large inclined wheels and self-equalizing steel side-frames—so that each wheel always bears its rightful proportion of the load. They are equipped with shock-absorbing Hyatt flexible Roller Bearings—which make the trolleys easy-starting, easy-rolling and long-lasting. Full information and descriptive literature on request.

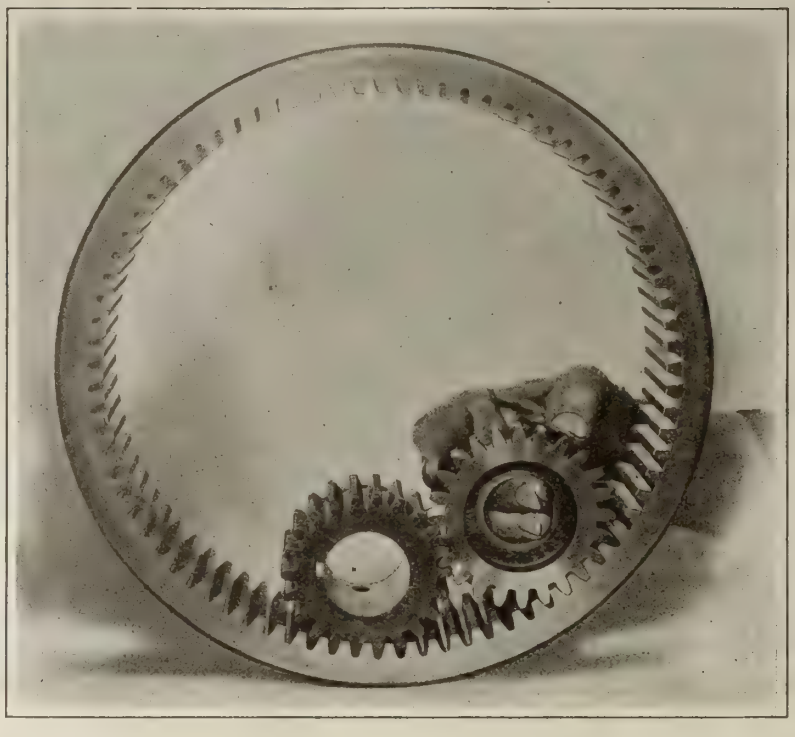
The Universal Cutter



Illustrating Universal Application of the Gear Shaper Cutter. Note—Cutter meshes accurately with internal gear and also with pinion, and will generate accurate interchangeable involute gear teeth on each.

The Gear Shaper cutter is acknowledged as being designed on the correct principle for generating involute gear teeth, but the Gear Shaper cutter is more than this. It is a universal cutter; it will cut any form of gear from a 12-tooth pinion to a rack—and either external or internal.

The illustration shows the Gear Shaper cutter in mesh with a pinion and an internal gear. This same Gear Shaper cutter will produce the teeth on both with theoretically correct accuracy.

The Gear Shaper cutter is not limited to the cutting of gear teeth. It is adapted to the generating of other shapes, such as cams, ratchets and other irregular shapes.

No other gear cutting tool possesses the possibilities of the Gear Shaper cutter from the standpoint of either accuracy of reproduction or low cost of production. Coupled with its many features is a service which has no equal in the gear cutting field. You will need this service more than ever now, because of the great competition that will inevitably come with peace.

Our Engineering Department stands ready to help you with your problems. Their assistance is given gratis. Submit your blueprints for suggestion to

INTERNAL AND SURFACE GRINDING

If you do surface or internal grinding, one of these three will handle your work to best advantage.

The CYLINDER GRINDER will take care of all work that cannot be rotated to advantage, such as two, four or six cylinders en bloc, and awkward large size castings of any material.

The INTERNAL GRINDER produces absolutely accurate holes, either straight or taper, in hardened steel, iron or bronze. It is ideal on bushings, gears, collars, ball bearing races and a thousand other parts, where accuracy and production are essential.

The SURFACE GRINDER delivers at a commercial rate a mirror finish on keys, rings, cutters, dies, discs, collars; in fact any shaped part whose size is within the capacity of the chuck.

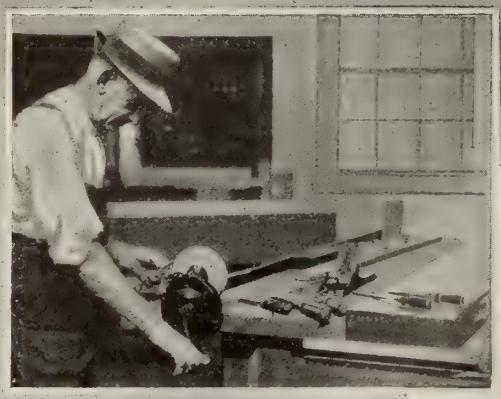
CARBORUNDUM NIAGARA GRINDERS

JUST TO REMIND YOU THAT YOU CAN SELL THEM



To the Carpenter

For grinding his chisels, plane, bits, gouges, etc. The No. 3 Niagara just suits him. It's big enough for bench work, small enough to pack in his tool kit.

To the Garage Man

For grinding parts, tools and fittings—for a dozen and one jobs about the shop. He will want the big No. 4, or, if he has power, the No. 28 Grinder Head.

To the Farmer

For grinding his scythes, grass hooks, mower sections, feed chopping knives—for edging spades and general farm tools, for grinding household knives, etc., the Niagara No. 14 is the machine for him.

To the Householder

For grinding household knives and tools —a little No. 1 machine.

The business is waiting for you—go after it with Carborundum Niagara Grinders. Carborundum displays and advertising will help you.

THE CARBORUNDUM COMPANY

NIAGARA FALLS, N. Y.

"One man does the work of eight".....

"We formerly cleaned off the mineral oil from these pumps with gasoline.

"We had to clean them both before and after assembling and it took *eight* men to do it.

"Now we clean them *once* with Oakite and *one* man does as much work as eight men used to do.

"We have eliminated gasoline with its dangers by cleaning with Oakite.

"We have also eliminated the handling of our total product once.

"We save seven men's time and get cleaner work than we ever did before."

This Advertisement is one of a series based on actual occurrences.

CUT YOUR CUTTING COST WITH VICTOR Flexibles

The high cost of tools should emphasize more than ever the importance of quality.

The high cost of hack saw blades ought to drive every hand blade user over to the saw that does not break in ordinary hand work.

VICTOR FLEXIBLE HACK SAW BLADES have exactly the same cutting power as the finest All-Hard on the market, and that they cannot be broken in use except by intentional abuse is an undisputable fact—which will represent a saving from twenty-five percent to thirty-three and one-third percent in breakage alone.

Seventy-five percent of the All-Hard blades used in hand frames break before they are worn out. Watch the All-Hard blades in your own shop and see the enormous amount of breakage—then use VICTOR FLEXIBLES and note the economy.

VICTOR SAW WORKS LTD - HAMILTON, CANADA

Standard the World Over

"THE RACINE"

HIGH SPEED METAL CUTTING MACHINE

Reduces Blade Expense

Aside from its ability to turn out more work than any other metal cutting machine, "THE RACINE" will save you considerable money on blades alone—enough to pay for itself in a reasonable time. The automatic lifting device is responsible for that. It automatically raises the blade on the return stroke, relieving it of all dragging or strain. This also means quicker cutting, less power used and greater production.

There are many ways "THE RACINE" will prove a big saving. Let us tell them to you.

Use "Racine" H.S. Tungsten Power Blades

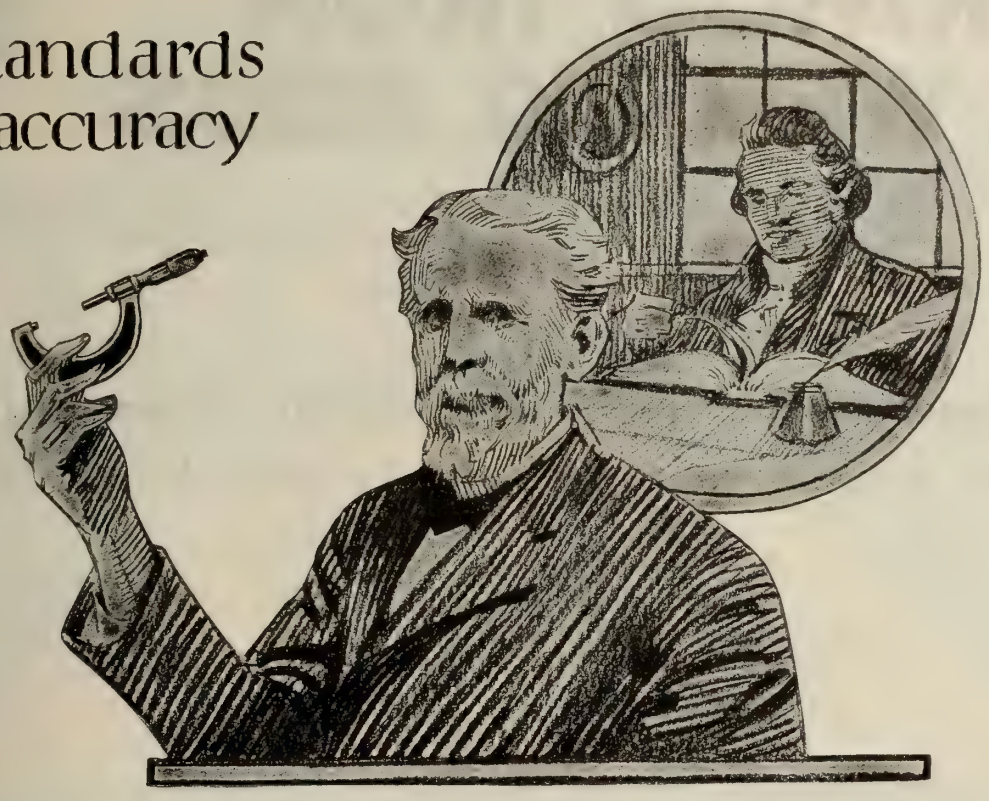
Standards of accuracy



Starrett Tools

are made according to the standard set by Noah Webster in 1828, when he defined accuracy—

"In exact or careful conformation to a standard of requirements, the result of care or pains; free from error, failure or defect."

Two generations of machinists have applied that definition to tools that bear the Starrett name—and found it fitted.

Every Starrett Tool is warranted free from error, failure or defect.

Catalog No. 21"3" gives details of the 2100 tools that comprise the Starrett line.

ARMCO IRON WELDING RODS

AMERICAN ARMCO INGOT IRON

The trade mark ARMCO carries the assurance that iron bearing that mark is manufactured by the American Rolling Mill Company with the skill, intelligence and fidelity associated with its products, and hence can be depended upon to possess in the highest degree the merit claimed for it.

cost somewhat more than ordinary filling material, but compared with the total cost of the weld, the difference is insignificant. The difference in strength and safety of the weld, on the other hand, is of vital importance.

"It has not been difficult to show them the economy of Armco Iron Wire—"

AIR REDUCTION SALES COMPANY

AIRCO

SALES DEPARTMENT 120 BROADWAY NEW YORK April 8th, 1919.

Page Steel & Wire Company
30 Church Street
New York City

Subject: Armco Wire - Result of Test.

Dear Sirs

We are more than pleased with the splendid results that we have obtained in our sales campaign of Armco Wire. This product has been offered by us through our local branches located throughout the United States from Seattle to Boston to a large number of our customers, and after thorough tests has been accepted by them in the face of a slightly increased first cost as compared with other products on the market. It has not been difficult to show them the economy of Armco Wire, despite this initial slight increase in its cost.

In this connection we enclose a letter from Mr Walsh of the Newport Shipbuilding Company which we thought might be of interest to you.

Yours very truly

W. L. Walsh
Sales Manager

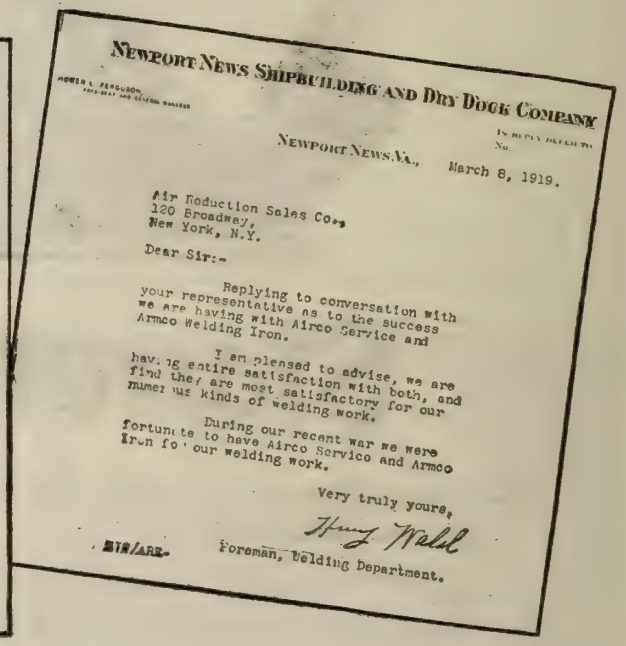
WLM:VW

Enclosure



NEWPORT NEWS SHIPBUILDING AND DRY DOCK COMPANY

NEWPORT NEWS, VA., March 8, 1919.

Air Reduction Sales Co.,
120 Broadway,
New York, N.Y.

Dear Sir:-

Replying to conversation with your representative as to the success we are having with Airco Service and Armco Welding Iron.

I am pleased to advise, we are having entire satisfaction with both, and find they are most satisfactory for our numerous kinds of welding work.

During our recent war we were fortunate to have Airco Service and Armco Iron for our welding work.

Very truly yours,

Henry Walsh
Foreman, Welding Department.

HW/ARE.

The above typical letter to one of our distributors shows that the superiority and real economy of ARMCO welding material are readily appreciated. Welders who use ARMCO IRON exclusively have a big advantage over competitors who buy inferior filler and their customers soon learn the difference.

Another ARMCO advantage from the welder's standpoint is the fact that one kind of rod of guaranteed Armco analysis is specially treated for oxy-acetylene welding and will do all the work (with better results) that heretofore has required a choice of one from many compositions. This means that with a much smaller investment for stock of filling material a shop is fully prepared to handle the usual run of steel and iron welding work.

Because of their exceptional purity and even density Armco Iron Welding Rods flow freely, weld evenly ,and give a joint that lends itself perfectly to hammering, forging, and, where necessary, to annealing and quenching.

Our booklet on "Armco Iron Rods and Wire" is full of interesting and useful welding data. Send for it.

TYPE K HIGH SPEED STEEL FURNACE

The Right Furnace for High Speed Steel

Too much—too little or an uneven heat treatment of High Speed Steel renders it practically worthless for the purpose intended.

This Gilbert & Barker furnace has been designed especially for the correct heat treatment of High Speed Steel. A temperature of 2400°F. is quickly obtained and **easily maintained.** The heat is uniform on all sides of the work and loss by radiation is reduced to the minimum by special insulation.

More than 50 years' experience in designing and building furnaces, especially for the accurate and economical heat treatment of metals is your guarantee of satisfaction.

PROMPT DELIVERY ON G. & B. FURNACES

Recent additions to our plant, already one of the largest in this field, makes it possible to offer immediate shipment of your order.

Tell us your problem and we will tell you the type of furnace you require, but first send for Bulletin 24. To-day is a better day than to-morrow--write.

The "Boehm" Positive Opening Threading Die

Hardened and Ground Guides for the Chasers

This Is One Distinct Feature of the

"Boehm"

The "Boehm" Positive Opening Threading Die has a positive opening and closing cam action.

Chasers have the necessary radial movement to enable the die to open after the threading operation has been completed. They are supported by a cam ring throughout their entire length and width. Incidentally—

The chasers slide between hardened and ground guides, and are supported by carriers which have a groove in the outer end for the positive opening cam.

This cam, the locking pins, and the "float" have features that add to the distinctiveness of the "Boehm."

We will be glad to send you complete description.

THERE IS "A REASON WHY"

When Germany signed the Armistice, Walcott Lathe Company accepted cancellations of orders for Lathes amounting to hundreds of thousands of dollars. Not one cent of damage from the United States Government or anyone else was claimed on account of the cancellation.

YOU SAY, WHY

Because Walcott Lathes are standard equipment throughout. They are built and designed for manufacturing purposes in sizes to meet every requirement of your shop. Thus, we have had a constant increasing demand for Walcott Lathes for the past thirty-eight years, not from one section of the country, but from all over the world. Our business is good, and our plant is running full time, not a man idle.

If you are interested in new Lathes, specify the WALCOTT, and you will find by their many advantages "The Reason Why."

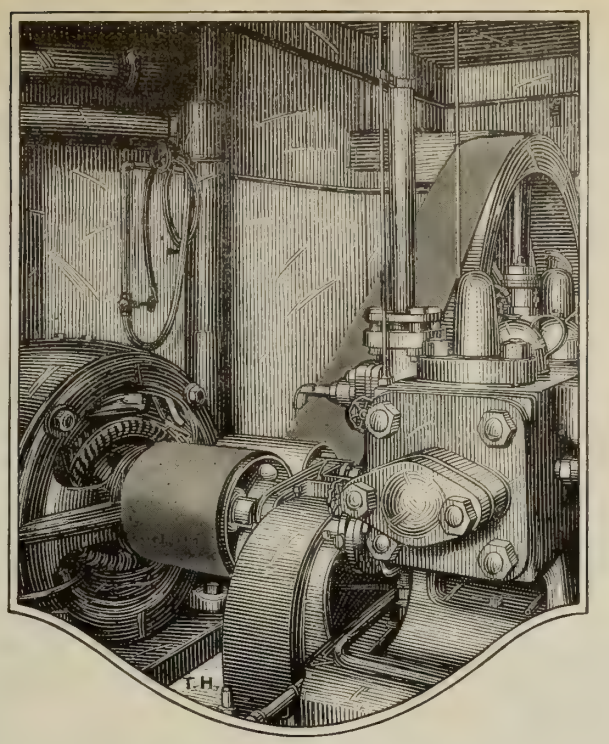
Do you know that the centrifugal force in belts at high speed reduces their driving power until at about 9600 R. P. M. a belt is incapable of transmitting power? All such factors are taken into account by our Engineering Department when they design standardized belt drives. Consult them about your problem.



This is a 12-inch Spartan Double Belt, operating a 50 horse-power Gas Compressor. Its cost to date is ½c per horse-power per week. When this belt had been in use 18 months, the engineer wrote us that it had given double the length of service of belts previously used. This has now been in use over four years and is still going strong.

TOP NOTCH

There is another case where top-notch efficiency and economy have been obtained by simply installing the right belt for the work to be done.

For many years Spartan Belting has been dominating the hard drives that destroy other belts. That experience ranks it as top notch in leather, in tannage and in workmanship. It is unusually pliable, wonderfully elastic, it is the greatest of pulley grippers and without an equal for high speed, overload drives or where unfavorable conditions exist.

Spartan well exemplifies the three principles back of Graton & Knight Standardized Series Leather Belt: First, they are made of the right material—leather. Second, they are tanned in our own tannery specifically for belting use, thus assuring the right kind of leather. Third, they are graded into a Standardized Series—a belt for each class of power transmission requirements—standardized in manufacture and standardized for the work to be done.

Certain articles can be tested in a short time—not so belting. It takes years to test out the correctness of principles applied in power transmission. The result of 60 years test of experience is that Graton & Knight Standardized Series Belting, the highest in grade, is also the most widely sold. That is a significant combination: highest quality—largest sale.

Many of the best belted plants ask us to specify the belting for every drive. Try the plan yourself. Then, when buying, call for "Graton & Knight—— Brand or equal." This won't commit you to buying our belts. It will put your buying on the one basic consideration—the work to be done.

Every Hour He Grinds 50 Tapered Bushings

Compare this output with the best performance possible on a lathe. The limit is half-a-thousandth and the operator turns out 450 cast iron bushings in a 9-hour day.

NORTON

This machine is only one of 13 Norton Grinding Machines in the King Sewing Machine Company's plant at Buffalo. The material is cast iron, size 1/22 in. long and 1½ in. dia., tapered 0.00005 in.

From .008 in. to .010 in. of stock must be removed so you will realize that modern Norton Grinding is not the old style polishing operation. The operator uses two arbors and two dogs so that the machine stops only long enough to take out the work and start up again.

The work comes from the lathe immediately after the roughest kind of a roughing-out job so that the Norton saves the time necessary for a finishing lathe cut.

We'll be glad to tell you more about the elimination of the finishing lathe cut. Write us to-day.

Builders of Standard and Automatic Turret Lathes, Vertical and Horizontal Boring Mills, Tool Grinders, Small Tools, Special Machinery, etc.
Eastern Sales Office: 30 Church St., New York. *Works: Madison, Wis., Warren, Pa.*

CANADIAN AGENTS: The Canadian Fairbanks-Morse Co., Ltd., St. John, Quebec, Montreal, Ottawa, Toronto, Hamilton, Windsor, Winnipeg, Saskatoon, Calgary, Vancouver, Victoria

Machinery Stock List

LATHES

Quan. Sizes and Description.

1—16" x 8' Reed Prentice Geared Head Lathe, with quick change gears, compound rest and full standard equipment.
1—18" x 8' Cincinnati Engine Lathe, with quick change gears, double back gears, three step cone pulley, compound rest and full standard equipment.
1—18" x 8' Perfect Engine Lathe, with quick change gears and double back gears, compound rest and full standard equipment.
1—18" x 8' Stevens Engine Lathe, with single back gears, plain change gears, compound rest and full standard equipment.
1—(Used) 48" x 26' New Haven Type Lathe, taking 20 feet between centres, having 48" face plate, supplied with adjustable face plate jaws, single back gears, compound rest and full equipment.
1—9" x 4' Seneca Falls Tool Room Lathe, with oil pan bed, plain change gears, compound rest and full standard equipment.
1—16" x 8' Reed Prentice Geared Head Lathe, with quick change gears, compound rest and full standard equipment.
1—16" x 6' South Bend Engine Lathe, with taper attachment, single back gears, plain change gears, compound rest and full standard equipment.
1—16" x 8' McDougall Engine Lathe, with quick change gears, 4 step cone, single back gears, compound rest and full standard equipment.
1—18" x 10' McDougal Engine Lathe, ditto, with same equipment as above machine.
1—20" x 10' McDougall Engine Lathe, with double back gears, quick change gears, compound rest, steady rest and full standard equipment.
1—20" x 10' McDougall Gap, with double back gears, quick change gears, compound rest and full standard equipment.
1—26" x 12' McDougall DBG and QCG Engine Lathe.
1—18" x 8' Greaves Klushman DBG and Semi-QC Engine Lathe.
1—18" x 8' Rae DBG and QCG Engine Lathe.
4—17" x 6' Leblond ditto (used).
1—Greenfield No. 107 Speed Lathe, 4' bed.
1—Greenfield No. 140 Hand Screw Machine.
1—Dalton 6" x 30' 3-Step Cone Bench Lathe, with C/S.
1—Perfect 12" x 8' Gap Lathe.
1—14" Mulliner Taper Attachment.

SHAPERS

2—16" "Walcott" Back Geared Shapers, with vise, countershaft, etc.
2—20" "Walcott" Back Geared Shapers, with vise, countershaft, etc.
3—20" McDougall Back Geared Shapers, with vise, countershaft, etc.
2—24" McDougall Back Geared Shapers, with vise, countershaft, etc.
2—Smith and Mills 28" Back Geared Shapers, single pulley drive.
1—McDougall 24" Back Geared Shaper (power down feed).
1—McDougall 20" ditto, plain.
1—McDougal 16" ditto, plain.
1—Walcott 16" ditto.

GRINDERS

2—No. 6 Perfect Grinders, complete, Cap 12 x 2" wheels.
2—No. 8 Perfect Grinders complete, Cap. 18 x 3" wheels.
1—No. 2 Blount Grinder complete 10" x 1½" wheels.
2—No. 1 Norton Universal Tool and Cutter Grinders.
1—No. 3 Brown and Sharpe Cutter and Reamer Grinder.
1—No. 2 Brown and Sharpe Surface Ginder.
1—No. 1 Brown and Sharpe Universal Grinder.
1—No. 1A Wells Drill Grinder, complete.
3—Gisholt Universal Tool Grinders complete.
2—No. 4 Perfect Grinder Heads.
2—No. 10 Perfect Grinder Heads.
1—No. 10 Perfect Comb Grinder and Buffer.
1—No. 1 Blount Grinder complete, 8" x 1½" wheels.
1—No. 2 Blount Grinder and Buffing Machine.
1—Type O.A. Worcester Drill Grinder complete.
2—Gisholt Universal Tool and Cutter Grinders, regular equipment.
2—Stevens Universal Tool and Cutters.
1—Murchey Chaser and Disc Grinder (used).
1—Gardner No. 4 Disc Grinder.
1—Perfect Disc Grinder.
1—Greenfield No. 1A Drill Grinder.
2—Perfect No. 4 Grinder Heads with C/S.
1—Perfect No. 5 Head and C/S, with adj. guards.
3—Perfect No. 6 Grinders, with adj. guards.
1—Perfect No. 8 Grinder, 18 x 3 wheels, with adjustable guards.
1—Perfect No. 6 Grinder Head.
1—Perfect No. 8 ditto.
4—Burtch Bench Grinders, with groove pulley and 2 4 x ½ wheels.

ELECTRIC GRINDERS

3—Dumore Electric Grinders., 110 V., Type 2A.C., 1/6 H.P.
1—Dumore Universal Grinder, 110 V., No. 1, ⅛ H.P.
1—Type J., 110 V., D.C., U.S. ½ H.P., Parallel Grinder (used).
1—Type J.H.A., 110 V., A.C., U.S. ½ H.P., Parallel Grinder (used).
6—Dumore Electric Grinders, 110 V., Type 2 A.C., 1/6 H.P.

DRILL PRESSES

1—5/16" McKenzie Column Drill.
1—5/16" McKenzie Sensitive Bench Drill.
2—14 Perfect Column Drills, No. 1 M.T.
2—15 Perfect Bench Drills, No. 1 M.T.
1—16 Perfect Column Drill, No. 1 M.T.
2—17 Perfect Bench Drills, No. 1 M.T.
2—18 Perfect Bench Drills, No. 1 M.T.
1—Model L-1, Cap ⅜", H.S. Detroit Sensitive Ball Bearing Drill.
3—20" McDougall Back Geared Drills, No. 3 M.T.
1—16 Hoefer Column No. 2 M.T.
1—Model L., Cap ⅜", H.S. Detroit Sensitive Ball Bearing.
1—21" Hoefer Vertical Drill, No. 2 M.T.
1—No. 65 6-ft. Moline Multiple Spindle Drill.

ELECTRIC DRILLS

2—Type A.U., Cap. 3-16", 110 V., "Universal" U. S. Elec. Drills.
3—Type B.U., Cap ¼", 110 V., "Universal" U. S. Elec. Drills.
2—Type C.U., Cap ⅜", 110 V., "Universal" U. S. Elec. Drills.
2—Type D.U., Cap. ½", 110 V., "Universal" U. S. Elec. Drills.
1—Type E.U., Cap ⅞", 110 V., "Universal" U. S. Elec. Drills.
2—Type 2.U., Cap. ¼", 110 V., "Universal" Standard Elec. Drills.
2—Type 6.U., Cap ¾", 110 V., "Uiversal" Standard Elec. Drills.
1—Type 8.U., Cap 1", 110 V., "Universal" Standard Elec. Drills.
1—Type C.B., Cap ⅜", 110 V., D.C. (used) U. S. Drill.
1—Type C.B., Cap ⅜", 220 V., D.C. (used) U. S. Drill.
4—Type 6-U., ¾", 110 V., Universal Standard Drills.
3—Type 10-U., 1¼", 110 V., Universal Standard Drills.

DRILLS

3—No. 3 McDougall 20" Back Geared Drills.
1—Natco 20 Spindle No. 37 Drill (used).
1—Henry and Wright Class "K" 12" Overhand Drill.
2—Perfect No. 16 Drills.
1—Avey No. ½ H.S. Bench Drill.
1—Reed 4 Spindle Drill 7" Overhang Slide Table, 32" x 12" (used).
1—Prentice 3 Spindle 6½ Overhand Slide Table, 26" x 12" (used).

POWER HACK SAWS

1—6" x 6" West Haven Acme Power Hack Saw.
6—No. 0 6" x 6" Perfect Power Hack Saws.
2—No. 3 6" x 6" Perfect Power Hack Saws.
1—No. 2 5" x 5" Perfect Power Hack Saw.
2—No. 0 6" x 6" Perfect Power Hack Saws.
2—No. 3 6" x 6" Perfect Power Hack Saws.

HACK SAWS

1—Acme 7 x 7" High Speed Hack Saw.
1—Peerless 6" x 8" High Speed Hack Saw.
1—Perfect No. 3 6" x 6" High Speed Hack Saw.
6—Racine No. 1 6" x 6" High Speed Hack Saws.

MILLING MACHINES

1—No. 0 Brown and Sharpe Plain Milling Machine with pump.
4—Kempsmith No. 3 Universal Millers.
1—13½" Kempsmith Universal Divinding Head.
1—10½" Kempsmith Universal Dividing Head.
1—Garvin No. 21 Plain Miller (used).
2—Burke No. 1 Bench Millers.

BORING MILLS

1—Fosdick No. 0 Horizontal Boring, Drilling and Milling Machines.

PIPE CUTTING MACHINES

1—No. 1 McDougall Pipe Machine, cuts pipe ¼" to 2" inclusive, with quick opening, adjustable dies, and standard equipment.
1—No. 2 McDougall ditto, Cap. 1" to 4".
1—No. 3 McDougall ditto, Cap. 1½" to 6".

CUTTING OFF AND FACING MACHINE

1—6" Facer Victoria.
1—Hall 6" Cutting Off Machine.
1—Hall 4.5" ditto (used).

CUTTING OFF MACHINE

1—No. 6 Nutter and Barnes Automatic Metal Cutting-off Machine, capacity round stock 5¾"; square stock 5¼"; I Beams 8"; 1" Rods, 13 pieces; 1½" Rods, 13 pieces; with regular equipment.

PRESSES

1—Brown Boggs No. 200 Plain Press, inclinable.
1—Brown Boggs No. 2½ O.A. Press (used).
1—Brown Boggs No. 150 Plain Press, inclinable.
1—Perrin 120-ton Hydraulic Press, 12" (used).
1—Ditto 75-ton, 10" (used).

FURNACES

1—Mecol 45" Nosing Furnace.
1—Hoskins G, 32" Furnace.

WOODWORKING MACHINERY

1—78 Cowan Foot Lathe Mitre Machine.
1—212 Jackson Cochrane Chair Seat Fitter.
1—Jackson Cochrane Two Drum Sander.
1—38" Crescent Band Saw, with guards.
1—No. 8 Morgan Nailing Machine (used).
1—No. 3 American Mortiser, Belt Driven.

SCREW MACHINES

1—No. 140 "Wells" Hand Screw Machine, turns 5" length, swing over ways 11", diameter of hole in spindle 1⅛", maximum capacity of push-out collet ⅞", diameter of Turret holes 1", with regular equipment.

ELECTRIC SCREW DRIVER

1—Type V.S.U., 110 V., Electric Screw Driver (used).

ELECTRIC TOOLS

5—Dumore Grinders, style "A" attach., 110 volt.
1—Do., Do., "B" attachment.
1—U.S. Elec. Tool Co.'s Type G.U. 1¼" Drill.
1—U.S. Elec. Tool Co.'s Type E.U. ⅞" Drill.
1—U.S. Elec. Tool Co.'s Type D.U. ⅛" Drill.
1—U.S. Elec. Tool Co.'s C.U. ⅛" Drill.
1—U.S. Elec. Tool Co.'s Type B.U. ¼" Drill.
1—Black & Decker Type "C" 110 volt, ⅜" Drill
1—Black & Decker Type "D", 110 volt, ½" Drill.
1—Dumore Type 1, A.D. 3/16" Drill.

BOLT CUTTERS.

1—Landis 1½" Single Head Bolt Cutter Style "F" with holders, pump, countershaft and wrench equipment.
1—2" Landis Bolt Cutter Head.

PUNCHES AND SHEARS.

8—No. 150 Brown and Boggs Inclinable Open Back Presses, Cap 1½" hole x 16 gauge steel with fly wheel.

BALERS.

1—Camoo 18" x 18" x 14" Paper Baler.
1— " 30" x 15" x 28" Paper Baler.

MISCELLANEOUS.

1—Rickert Shafer Tapper, ¼" Vertical Type.
1—Dinge No. X Separator, 110 volt, D.C., Elec. Magnet (used).
1—Berkshire Manufg. Co.'s Moulding Machine (used).
1—Horizontal Tapping Machine, small (used).
1—St. Louis Tapping Chuck.
2—Four Sides Tool Posts for 20" Cincinnati Lathe.
4—Compound Rests for 20" Cincinnati Lathe.
1—High Speed No. 4A Hamer 4.5 Shells.

Building 5-inch Gun Mounts at Brantford

In Our July 24th Issue We Published the First Portion of This Article—Further Operations Are Now Described, Until the Mount is Finally Completed and Inspected.

By J. H. MOORE, Associate Editor Canadian Machinery

Before going into the details of the second portion of this article, let us summarize just what parts we have touched on. As will be remembered, we touched on the operations on the stand, training ring, carriage, and slide, finishing up at this portion. So now, since we have reviewed up to this point, let us go still further into the remaining portions of this mount. To allow readers to familiarize themselves with the technical names of some of the important parts, let us refer to Fig. 1, and note what the various letters shown on this photo illustrate.

A is a large steel casting technically termed "The Yoke." B is termed the telescope holder. C the elevating and depression hand-wheels. D is what is termed the sight bar head, while E is where the support bolt of recoil cylinder comes through. F and G are the support bolt holes for the recoil spring cylinder bolts. H illustrates one of the two recoil spring cylinders. I represents the elevating bracket casting. We will now leave this photo for the present, but will refer to it later in the article.

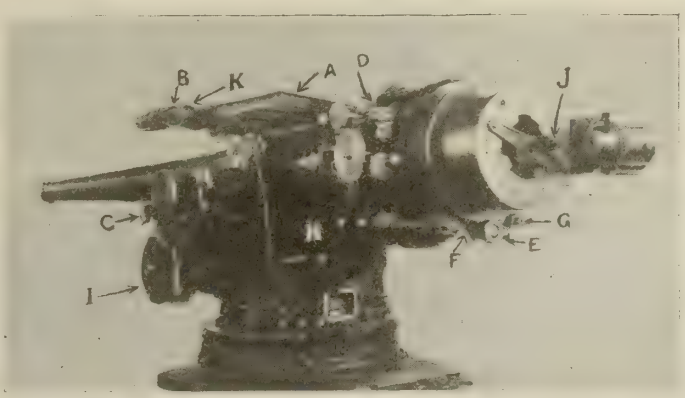

FIG. 1.—GENERAL VIEW OF THE GUN AND MOUNT.

The Yoke

The yoke is a very long and slender steel casting. The natural result is a casting very springy, and usually warped, so that the first operation on these parts is that of a straightening process.

To do this they are placed on a large frame of the shape that the yoke should be, when the parts which are warped are played on by an oil burner, when after being heated at these portions they are pulled down to the form by means of clamps, and allowed to cool. The work is then taken to the layout table, and marked off correctly. They are now roughed off on the shaper and planer, then drilled, but these operations are of the usual style. They are later taken to a converted planer, which has been turned into a vertical milling machine, and there various milling operations are performed. Another milling operation worthy of note is shown at Fig. 2. In this operation, the portion where the azimuth rack (as it is technically termed) is is milled, and this milled groove is on a very large radius, so that readers can readily understand what the pin A on the jig shown at Fig. 2 is for, namely, that the work pivots around this centre point. We have so far, in this view, not called the reader's attention to anything except the jig and the operation, but now let us speak of the machine itself. On first sight this looks like a vertical miller, but is it? On a second glance we see it is nothing more than a converted Le Blond Lathe, and a very clever conversion at that. Again proving that for special purposes, there is always a way out, providing, of course, you try hard enough to find it.

There are many other operations of special note that we cannot touch for lack of space, but will just mention a few before passing on to another part of the mount. The worm which fastens in the portion milled, (just spoken of in Fig. 2) is cut on a special machine for the purpose. The rocker is also scraped in, and friction strip fitted, when the yoke and its various detail parts are assembled.

The sight bar head will next be discussed, and in order to give the readers some idea of its general appearance, the photo at Fig. 3 was taken.

As can be readily understood by readers, this is a most important portion of the mount, and entails considerable accurate work before its completion. It will be noticed that this head is all finely graduated, and when it is mentioned that the scale on the dial A must tally up with the scale at slide B, or graduation strip as it is sometimes called, it will be realized just what this means, namely, that every operation throughout must be most carefully checked and followed up.

It will be noticed that there is a rack cut at C on this piece. This is accomplished on the miller by a special fixture for the purpose, which travels the work at the correct radius. A special indexing attachment is also part of this fixture. Another very interesting milling fixture on this portion is shown at Fig. 4. This fixture, by means of the handle A, travels in the correct radius to allow the portion B to be machined. The method of holding the work is self-apparent. This operation is done on a Le Blond Miller with splendid success.

At Fig. 5 we show still another milling fixture on this piece, completed on a Cincinnati Miller. This jig is constructed on the radius principle, all the work pivoting from the pin A, and swinging at the correct radius for the work. Numerous operations are performed on this principle, until the sight bar heads' completion. It might be interesting to mention that this portion is a drop forging of nickel steel, and originally weighs 150 pounds in its rough state. Before completion, however, it keeps reducing its weight operation by operation, until when completed it only weighs 40 lbs., a difference of 110 pounds, which, to say the least, is some difference. All these operations are from the solid, as this

piece must be without flaw of any kind. The groove seen on Fig. 5 at B is approximately 3½ in. wide, 1½ in. deep, milled out of the solid.

Recoil Cylinder

First, this cylinder is made from a steel forging, which comes to the factory in a rough-turned state. The various finish-turning and boring operations are then completed. A bronze bush is now pressed in place, after which a special shaped keyway is machined. This is not in a true measure a keyway, but rather a passageway for the glycerine, which goes inside of this cylinder for recoil purposes. Let us explain the action of this glycerine before going further.

When the gun is fired, naturally there is a sharp recoil. This would ruin the gun in short order if no provision were made to take up this jar, therefore, the reason for both the recoil cylinder, and the recoil spring cylinders, but let us, for the present stick to the recoil cylinder alone.

When the recoil cylinder is finally completed it is filled with a certain amount of glycerine. This acts in the following manner. Immediately at the start of the recoil, the piston inside this chamber has a tendency to rush back with great force. It does this in fact, for a portion of its length of travel, which brings up to the discussion of the possageway already spoken of. This groove is about 1½ in. wide at one end, but tapers down to ¼ in. wide at the other, the object being as follows: As the piston comes back, its speed is narrowing down, therefore, not allowing as much glycerine to go through as at the start, or the wide end of the groove. Naturally the more resistance offered to the piston the slower its travel, and the greater the cushion effect. The narrower the groove the less glycerine going through, and therefore, the greater the cushioning effect.

Before going on to the recoil spring cylinders and their functions, let us study Fig. 6, and see how these recoil cylinders are tested. They are placed on a wooden stand as shown, after all machining operations have been completed, and connected up to an oil pump to the left. It is now tested to a pressure of 3,300 lbs. for leaks. The idea of having glycerine in the tubes on the gun, is in order that they will not freeze up in cold temperatures. Perhaps it would be best to state that it is not pure glycerine that is contained in these cylinders, but a mixture of glycerine and water. The pistons for these cylinders are also forgings, and made from a special alloy steel.

Inspection

Before going on to the two remaining photographs let us see what methods of inspection are adopted.

From the very outset the system of inspection is most rigid, for one flaw might mean the loss of a ship. This may seem a rather wild statement, but when one considers that perhaps while a gun was training on its target it refused to act, that target, which, ten chances to one, is another ship, has an equal chance to fire on the ship with the jammed gun. For this reason the authorities are most strict in their tests.

To go over all these tests would occupy an article in itself, enough to say that special test stands and tables form a part of the inspection department, together with a regular host of gauges of all descriptions, pin, snap, and the other numerous varieties, feelers of very fine quality being frequently used. Even zig-zag cigarette paper is used in conjunction with the square, and this paper must absolutely refuse to draw at any point on the square.

Should any large size discussion arise as to the accuracy of any gauge throughout the plant, they have a Pratt & Whitney Precision measuring machine, all enclosed in its own particular compartment, which settles beyond a doubt the question of accuracy.

Scraping

The amount of scraping to be done on this product is surprising, the biggest part of this scraping being on the sight head and its component parts. This firm has trained men who knew nothing whatever of scraping into expert scrapers, turning out work that is a treat to look at, and accurate in all particulars.

Final Inspection of Gun

The gun mount is finally assembled on a special assembling stand, and the barrel, breech, telescopes and all attachments placed on the same. Fig. 1 illustrates this view clearly. The chief naval inspector now tests the gun for accuracy in the following manner. He first lines up the telescope H with the centre of the barrel. He then lines up this telescope with the cross marks, or targets shown in Fig. 6. After the gun is tested on these marks the barrel is elevated to run up the lines A and B, see Fig. 6. At top of these lines is a parallel line joining these two vertical lines, and the gun must now to be swung around on its base. with the sight on

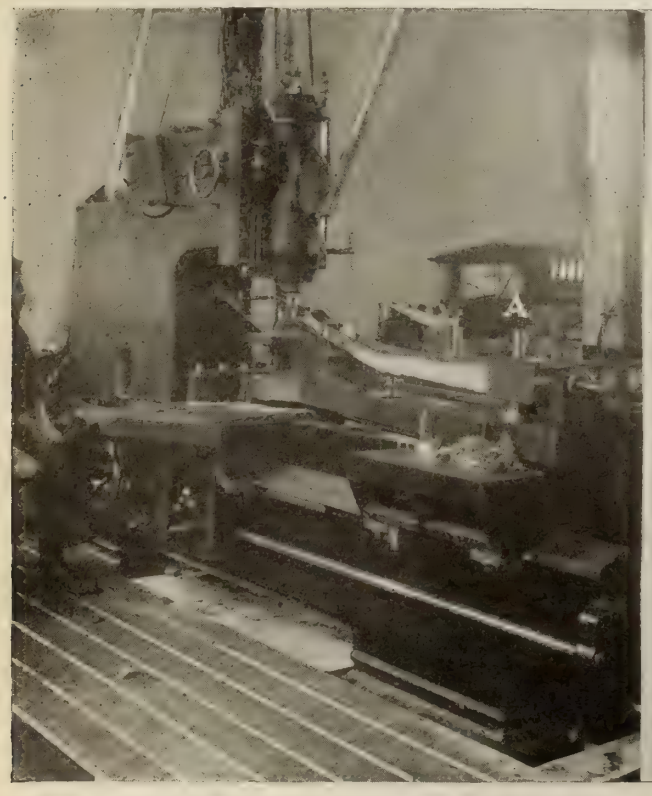

FIG. 2.—MILLING THE YOKE ON CONVERTED LATHE.

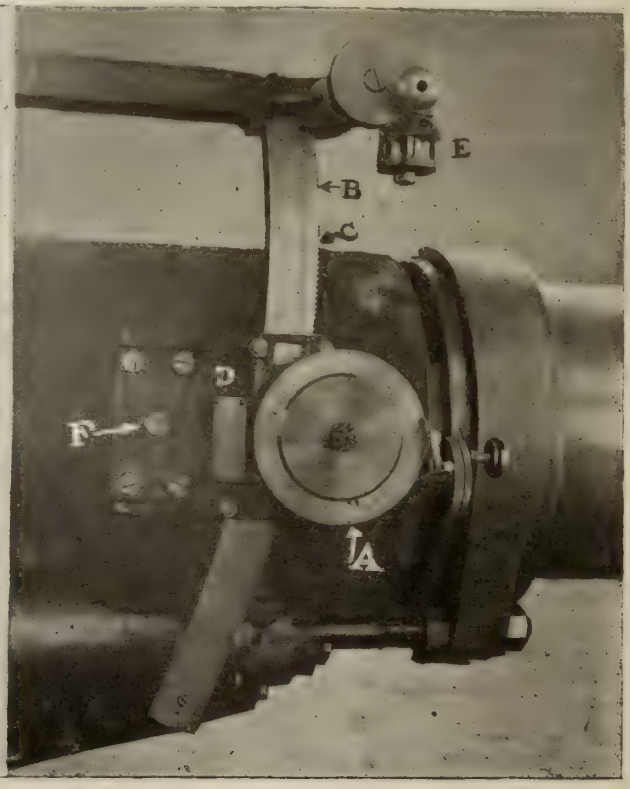

FIG. 3.—A CLOSE-UP VIEW OF THE SIGHT BAR HEAD.

the barrel never deviating from the mark, even by a hair's-breadth. Should the alignment not be perfect, the gun is disassembled if necessary, and the change made to ensure absolute accuracy.

As the readers will note, accuracy and interchangeability of all parts must be had, and is essential on all component parts entering the completed mount, as any damage which might be attributed to gun-fire from the enemy can be instantly repaired by removing the damaged parts and replacing same with similar spares in stock. In order to attain the foregoing, two important factors must be contributed:?

(1.) The manufacturers at Dominion Steel Products Corporation have contributed their ingenuity through the use of excellent standard fixtures, which parts so assembled in same and completed, must be interchangeable, through the system of coast inspection after each operation.

(2.) The Government or final inspection insures that all the drawing dimensions are kept within the prescribed tolerances allowed, and this inspection is attained through a United States Government office.

The Naval Inspector at Munhall has charge of the inspection throughout the several middle Atlantic States and that part of Canada extending from Detroit to Montreal, Brantford, Toronto and Hamilton, coming under the cognizance of the Munhall Office, and commanded by Commander R. R. Adams, U. S. Navy.

The Munhall district is divided into four sub-divisions, of which the northeastern sub-division is located with headquarters at Erie, Penn., under Lt.-Commander C. H. Fischer, U.S.N. Rt., with a corps of assistants and sub-offices scattered throughout this district. The officer in charge at the Brantford plant is Ensign F. J. Chatel, and the inspectors are largely enlisted personnel trained at Great Lakes Naval Station, and civilian sub-inspectors.

Before leaving this article, the writer believes that some particular mention should be made of this inspection staff, so, to give readers an idea of the staff and its leader, we illustrate at Fig. 7 the inspection department as far as the sailors are concerned. The gentleman marked with a cross is the ensign himself, and a brief sketch of his experience would not be amiss.

His name, of course, comes first. Ensign F. J. Chatel, U.S.N.R.F., comes originally from Detroit, Mich. He is a graduate of Michigan University of Mechanical Engineering. Started as an ordinary sailor, but by energetic work obtained his commission at sea. Has been 1½ years at sea. He received his commission on April 7th, 1917 on board the U.S.S. Huntington. On this ship he had charge of a division of engineers. Such an experience, as readers will agree, well fits a man to handle important work such as he is now concerned with.

To put it briefly, we can say without any attempt at flattery, that first, the Dominion Steel Products Co. are turning out a great product in a great way, and Ensign Chatel and his staff are helping in a like manner to ensure the accuracy and usefulness of this product.

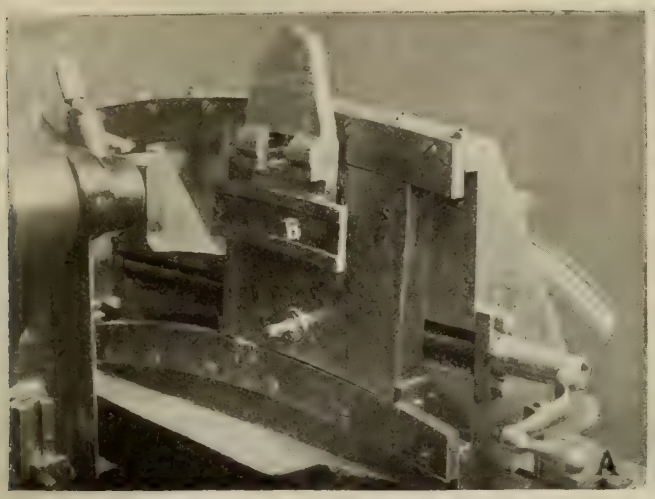

FIG. 4.—JIG FOR MILLING SIGHT BAR HEAD.

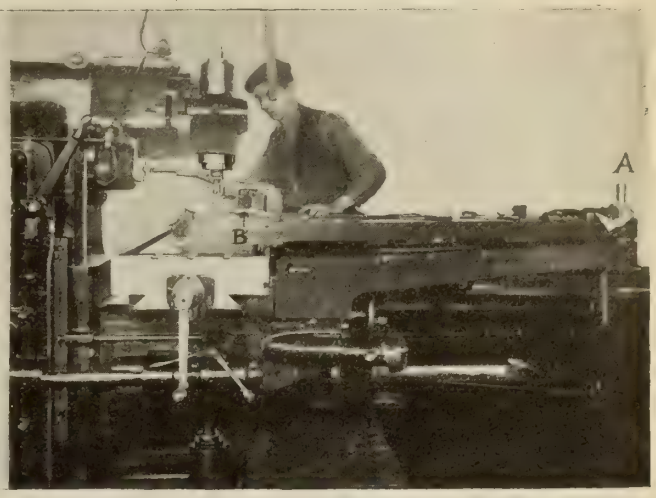

FIG. 5.—ANOTHER MILLING OPERATION OF SIGHT BAR HEAD.

It is stated that the Japanese are exploiting on a large scale the ores discovered in Korea, and are making extensions in their industries to handle this new source of supply. Ore concessions in China will further increase the Japanese raw material. A British correspondent predicts not only that Japan will soon be independent of outside sources of supply, but that in another ten years she will be exporting cheap steel to the Pacific markets, and even breaking into more distant markets like Great Britain.

FIG. 6.—A VIEW SHOWING THE SIGHTING END OF THE SHOP.

FIG. 7.—A GROUP OF U. S. INSPECTORS, TOGETHER WITH THE ENSIGN, MARKED WITH A CROSS.

Some Factory Sites Not Cheap, Even as a Gift

There Are Many Factors, All of Which Should Be Considered, if the "Free Site" is Not Going to Turn Into a White Elephant on Your Hands

ON the intelligent selection of a suitable habitat, much of the future of a new industry may depend. The factors governing this selection are so many and so diverse in their aspects, that it is quite easy to go wrong, even when the choice would appear to be quite obvious.

The erecting of a new manufacturing plant may be for the purpose of carrying on a new industry, or to provide needed space for a going concern. Again it may be to provide a branch factory for a firm whose main factory is in another country. Many examples of this latter case are found in the American firms with branches in Canadian territory.

While the choice of a suitable location is important to any industry, it is most so in the case of the business just entering the industrial world. This has all its connections yet to make, both on the buying and selling end, whereas the factory which is a branch of an already well established firm has a great deal of this question already solved for it.

Some of the Factors

What are the most important requirements for a factory plant? If these are known, then in the search for a location, some definite standard can be aimed at, and a process of elimination gone through.

The first of these requirements is geographic position in relation to supply of raw material, and the market for the finished product.

Transportation facilities would naturally be the next feature to be considered.

Labor supply, health statistics, educational facilities, general aspect of the immediate locality and its environments, and lastly, the cost of land and taxation assessments. These are put last because they are really the most easily surmounted difficulties. This is true, although sometimes they are considered first, and allowed to loom in importance over more vital points. There are hundreds of small towns vieing with each other to secure new industries and these towns are willing to offer very tempting inducements as far as land costs go. These offers are often so tempting that the seeker after new fields is inclined to look at the disadvantages through the wrong end of the telescope. Some of these offers approach the grotesque in their liberality. For instance a certain town offered recently to give an industry ten acres of land on a railway siding, build a one-storey fireproof factory containing 30,000 square feet on this land, and turn it over to the company free of water rates and taxes for ten years. In addition they are offered power at the rate of ½ cent per k.w.h.

Now an offer like this is really brilliant enough to dazzle anyone. On the other hand should it not make the thoughtful investigator pause and see why the municipality should offer to give away its ratepayers' property so freely? Sometimes it does, sometimes not.

While cheap land and exemption from taxation for a period of years is a consideration, it can be easily outweighed. For instance to take an extreme case, free land and taxes would not be much help to a lumber mill, if it was situated on a prairie. In a case like that the mill would be in a bad position, both in respect to its raw material and its finished product.

It is more important to be close to the source of raw material than to the market for the finished product. This fact really determines the case for certain kinds of industries. Lumber and pulp mills will always be found in situations such that the wood can be delivered from the limits by water. Steel mills will be in a position ensuring easy delivery from the ore deposits, preferably by water, ensuring cheap freight rates.

The advantage of close proximity to raw material sources rather than selling fields are obvious. Sales are made usually over a widely diffused area, whereas raw material is concentrated. In the case of transportation troubles arising, as often happens in this country in Winter, accessibility to raw materials is a boon.

Inability to ship finished products will lead to congestion in stock and shipping rooms, which is inconvenient, but if the raw material supply is cut off nothing else but shut-down can be looked for. Distance from supply means carrying of large stocks, which is again unfavorable, as it prevents advantage being taken of favorable changes in the market.

We have thus determined on some general qualifications, that the site selected must be easily accessible to the field of supply.

How About Transportation?

Transportation facilities are next to be considered. The municipality angling for the factory is almost sure to be able to offer a siding or spur into the factory grounds. This is very desirable but needs careful examination. If the town is on a branch line, with a poor freight service, the fact of having a siding is not such a help. It would be better to have a location in a town on a main line, even if some trucking has to be done between factory and freight shed. If freight service in the locality under consideration is good, and a siding can be secured, connecting with a main line of railway, then local conditions affecting transportation must be considered.

The climate of Canada in Winter is such that it must be considered very carefully in making selections. It is not always so considered, and neglect of this precaution has involved many manufacturers in much expense.

The factory may be reasonably close to the railroad, and be connected thereto by a siding, and that siding and its approaches may be a source of trouble for six months of the year. There are districts in Canada where snow is to be looked for in quantities from November until April. Local topography may be favorable to drifts, or otherwise, and for the former, one can readily see where the siding will be. Instances where the whole yard force of a factory are kept busy two thirds of their time during the Winter in keeping the tracks clear of snow are not hard to find. One case occurs to the writer where two factories were near neighbors. One had a siding and extensive trackage in the yard. The other had no siding. During the Winter the factory without the siding sent its product out on sleighs to the freight shed without a hitch. The other factory had its yard gang employed day after day opening up the track to get the freight cars in to the shipping room.

This point may not occur to one looking the ground over in Summer, but it is a real live question in many districts of Eastern Canada.

Power for the Plant

After the question of transportation comes that of power for the factory, and this is another question which requires careful consideration. If the product is such that a large amount of steam is required for process work all the year round, and heating in the winter, then it is likely that the installation of a steam plant would be advisable. If cheap electric power is available locally then careful consideration of the nature of the load will have to be made before the type of power is decided on. Here again the nature of the local climatic conditions should be carefully considered, and statistics over a number of years should be consulted.

Power may be cheap and plentiful, but the cost of

heating may be such as to overshadow the cost of power altogether. In such a case it is cheaper and better to generate the power on the permises, having the use of the exhaust steam for heating all Winter. The cheap power may be available in the Summer months, affording an opportunity for a thorough overhaul of the steam generating plant.

If Winter conditions are consistently bad, then the other advantages offered must be very great to outweigh this factor. If conditions in Winter are such that only a medium amount of heating is necessary, then the possibility of cheap electric power will be a great inducement. If a steam plant is to be installed, the question of obtaining the necessary coal must be studied.

Sizing Up the Labor Market

The amount and the type of labor in the locality is of course an important item. The general standard of living and education in the neighborhood will give an idea of the possibilities of getting intelligent help. Are the characteristics of the town such that a good class of labor can be attracted to it? Are the municipal authorities up to date, and capable of improving the standing of the place? Is the water supply good and is the hygienic standard of the town what it should be?

A town that already has some manufacturing plants in it is liable to furnish a better class of labor than one in which an industrial plant is a new feature.

The population of the latter is likely to be chiefly engaged in rural or semi-rural pursuits. This type takes but slowly to the work in the factory, and furthermore, there is but little reserve to draw on. A centre that has been the home of manufacturing plants for a good period is likely to have a floating population to draw on. Nearness to a large centre of population is undoubtedly a great help in the labor question, as far as ensuring a supply goes. The wage scale, of course, may be affected by the prevalent scale in the larger centre, but this is balanced by the better class of labor available. The cheap labor of the small rural town is often very dear. The men have to be trained and taught, and those who have the ability to learn quickly usually drift away as soon as they become useful. They go to the larger centres and exploit the skill they have obtained at the expense of the manufacturer in the small town. The prospect of future growth is also to be considered. Cases in which large plants have been erected in small towns with the idea that the presence of a large factory would stimulate growth, thus insuring a good labor supply, are fairly frequent. Sometimes it has turned out that way and again it has not. There is a case where after ten years the population of the town has decreased and the labor question is serious.

The trouble with a semi-rural population is that a large number subsist partially on the product of their own land. Their requirements are few and their ambition lacking in proportion. This class of labor have but little inducement to steady work. They are inclined to put in part time at the factory to help their income and refrain from working about an equal part. They are inclined to resent the introduction of strangers and make things uncomfortable for them. This attitude makes it difficult for the management to keep its forces up to strength.

Local conditions have a great influence on the filling of the higher positions in the factory. If housing accommodation is poor, sanitary arrangements not of the best, and educational facilities lacking, it is difficult to get the right kind of man to settle in the town. Even an enhanced salary will not attract, as the absence of the comforts to be obtained in better managed centres is weighed against the extra money. Out of date sanitary arrangements react on the general health of the workers, and causes a great deal of lost time through illness. Further it predisposes the population to epidemics, which may result in anywhere from 25 to 50 per cent. of the help being laid off for weeks at a time.

It can readily be seen that cheap land and exemption from taxation cannot begin to overbalance such drawbacks. Generally speaking a town that possesses real tangible advantages does not need to go to extremes in offering inducements to new industries, but there is no question that where there is competition between nearby localities for manufacturing plants, the manufacturer stands to get real concessions.

Opinions of Manufacturers

In view of the foregoing these following opinions from men in a position to speak with authority should be of interest:

"What is the best location for a factory? If you were beginning all over with the knowledge you now have, where would you locate?" Those were the questions which CANADIAN MACHINERY put to a half dozen leading manufacturers of Western Ontario, and to the Industrial Commission of the leading purely industrial cities in Canada.

It is the business of Mr. C. W. Kirkpatrick, Industrial Commissioner, of Hamilton, to be posted in such subjects; tnough, naturally, he is inclined to think that the questions can be answered with one word, "Hamilton!" Mr. Kirkpatrick would put labor supply first in the list of requirements, and, as a matter of fact, everyone interviewed held that view. "Some places seem to be better than others in this respect" said he. "'Hamilton is now a centre for the steel and iron industry, which requires male help exclusively. This leaves a surplus of female labor and provides for textile industries.

"If it is a large industry I should place a good supply of cheap power as next in importance. This has been a big factor in building up Hamilton. You know we had a hydro-electric of our own before Sir Adam Beck entered the field, and even to-day its rates are more favorable.

"Third place I should give to shipping facilities. We are served by lake and rail. Possibly the big manufacturer would rather be located close to his raw material rather than to his markets, though he is fortunate indeed if he can secure a location giving him both.

"A fourth advantage is to locate where there are other industries established, in a well known industrial centre. Finally need I say that the man seeking a factory location will realize that an industrial commissioner is necessary in any live centre. He not only brings in new industries, but acts as a buffer between the industries established and the municipality. There are always things coming up in every industrial community which have to be smoothed down, a work which is easier for our industrial commissioners than an alderman to do."

Col. Harry Cockshutt, of the Cockshutt Plow Co., Brantford, would put labor supply and freight rates as of nearly equal importance in choosing a location. "Western Ontario is the ideal location. Rates are better in the Western peninsula than in any other part of Canada, and the labor supply is exceedingly good."

"Location means nearly everything to a manufacturer, particularly on starting business in a small way," said Mr. John Muir, of Goold, Shapley & Muir, Brantford. "The average manufacturer, when starting business, needs all his capital to make a beginning and keep his business running until it is on its feet. He does not want to lock up a lot of money in building and real estate, which he should have liquid. Take our own case. About sixteen years ago we were almost wiped out by fire and the people of Hamilton tried to get us to go over there and take the old Singer Sewing Machine plant. Brampton also had an idle factory, equipped, and offered it to us free of rent and taxes. In that case the building was the big attraction to us, and we should have moved had not Brantford made attractive offers for us to stay. Freight rates were then better there than here, though at present there is no city in Canada better served by rail than Brantford.

"You can not induce manufacturers to come to a place unless you can show them that there is favorable accommodation. Recently there was a by-law passed here to guarantee the bonds of the Realty Co. This company proposes to build factories to order and offer them to American manufacturers looking for a Canadian location

at a rental to cover interest and sinking fund. The dividend of the Realty Co. is limited to 6 per cent.

"No manufacturer can afford to neglect the Ontario trade. Ontario has been the life of the Ontario manufacturer for years past."

Mr. Pock, of the Westinghouse Co., Hamilton, emphasized the necessity of amusements in a district to make it attractive to labor. Shipping facilities and cheap power were great essentials. In the Westinghouse business the line of raw materials used is varied, and it is hard for them to get near the source of supply. They can get their pig iron in Hamilton, but their copper comes from New England and their wire and cable from Montreal; so that in their case shipping facilities and labor supply are probably the most important considerations.

Mr. Hobson, of the Steel Co. of Canada, would put labor conditions as the prime requisite. Next, he considers nearness to consuming market, and third nearness to raw material. He looks on the location of his company as so favorable in all respects that it is hard to rank the conditions. "We can assemble our ores cheaper in Hamilton than they can in Pittsburgh," he said. "There is a great deal in being close to your market, however. Ordinarily, 75 or 80 per cent. of our products are consumed within a radius of 75 miles of Hamilton. We are in the hub of the manufacturing centre of Canada. When you are close to your consumers you can get the goods to them overnight, and in this we have the advantage over other steel producing centres. It seems to me that the great future of the steel industries in Nova Scotia is in the export trade. We could have made a great deal of money during the war by going deeper into the export business than we did, but we were anxious to look after our Canadian customers."

A toolmaker was confronted with the job of removing a bushing which was fitted very tightly in a blind drilled hole. There was not space enough at the bottom of the hole to get in a hook of sufficient strength to pull out the bushing. After several different methods had failed, the tool maker fitted a steel rod quite accurately into the bushing, filled the hole with heavy oil, inserted the rod and drove it in with a hammer against the oil. The fluid pressure of the oil was transferred to the inner end of the bushing, and forced it out with very little difficulty.

Centrifugal pumps for boiler-feed work, steam turbine driven by direct connection, are now to be had in small sizes. The pump, turbine, and supports are combined in a single unit. The solid shaft is hung in two ball bearings, and only one stuffing box is used. The packing between bearings and steam end is a floating carbon ring, the bearings being kept uniformly lubricated by a constant-level oiling device. An excess-pressure governor and a minimum-pressure safety stop make the operation practically automatic.

LOADING A 15-INCH SHELL INTO THE BREECH OF A HOWITZER AT THE FRONT BY MEANS OF A MORRIS SPUR GEAR CHAIN BLOCK

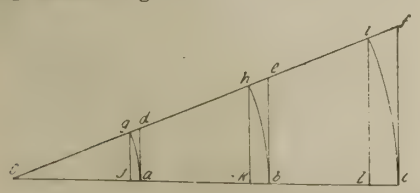
Shop Arithmetic, Geometry and Trigonometry

Ninth of a Series in Practical Mathematics For the Mechanic and Those Learning the Machinist Trade—The Present Article Takes Up the Subject in the Title.

By J. H. RODGERS

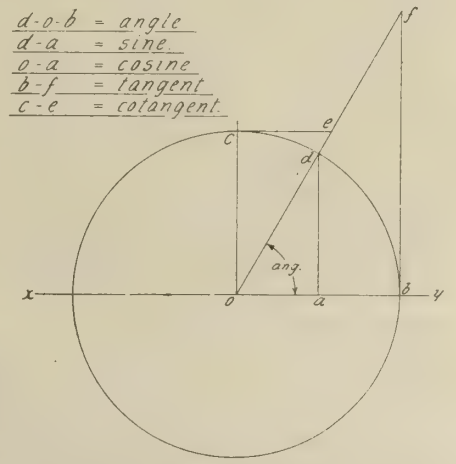
WHILE the mensuration of regular plain figures, as explained in our last lesson, is a comparatively easy process, there are occasions when other means must be adopted before a solution can be obtained. This is particularly true where angles are given in specified dimensions and a practical solution necessitates certain conversions so that the corresponding lengths can be determined from the other known factors. In the construction of jigs and fixtures it is frequently required to check the accuracy of certain calculations, and it is often necessary to figure out the distances between holes, or holes and surfaces, and to perform this work satisfactorily a knowledge of geometry and trigonometry is of vital importance. Do not let the mention of trigonometry discourage any reader who is not familiar with its application, as many shop problems can be made much easier if recourse to this branch of mathematics is resorted to. It is not intended that a complete treatise of this subject will be given here, but sufficient elementary principles will be dealt with to prove to the student the advisability of acquiring some knowledge of trigonometry, so that many shop problems may be tackled with greater confidence, and permit the workman with such learning to undertake many jobs that formerly were considered quite difficult.

Before giving any concrete examples we will endeavor to put the reader at his ease regarding certain fundamental details pertaining to the subject "trig." As the name implies, trigonometry is a treatise on the solution of triangles, and as every triangle has three sides and three angles, the purpose of "trig" is to find the dimensions of some of these angles and sides when those of the others are known. In a previous lesson on proportion it was shown that the corresponding lengths of lines of similar figures vary in direct relation to their position. This principle is the basis of trigonometry and all the constants used in this section of mathematics are determined with a circle of one inch radius. To illustrate the principle of "trig" the following sketch is given.



Suppose that the angle C-O-F is 20 degrees, and the lengths O-A-O-B and O-C to be 1, 2 and 3 inches respectively, it is clearly seen that all other similar lines are in the same relative proportion. In order that this subject should meet the every day requirements of the engineer and mechanic, tables have been prepared, and these can be found in any good technical text book, their degree of accuracy depending on whether the constants are given for degrees, degrees and minutes, or degrees, minutes and seconds, the last-mentioned being calculated for every 1/1296000 part of a quadrant of a circle. In general, the tables are invariably made out for degrees and minutes, the value of the seconds being calculated from the differences between the nearest minutes.

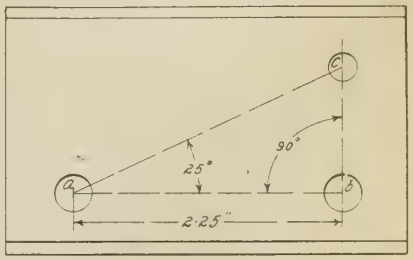
In the study of trigonometry there are several functions that determine the value of the respective angles and the lines by which the angles are formed. The most important functions are the sine—cosine—tangent—and cotangent. These are shown in the accompanying figure:



In the study of "trig." and in all tables of functions, it must be understood that the values given are based on angles calculated in a circle of one inch radius. To give a graphical illustration of the four functions given above, therefore, first draw the horizontal line X-Y, and with O as a centre draw a circle of one inch radius. Now suppose we desire to show the position and lengths of the functions for a 60 degree angle. Through the centre O draw the line O-F at an angle of 60 degrees. From the point D, where this line cuts the circumference of the circle, drop a line D-A perpendicular to X-Y. The line D-A will be the sine of the angle, and will be found by measurement to be .86603 of an inch in length. The length O-A will be the cosine of the angle and will be .5 of an inch in length. From the extremity of the one inch radius, or from the point B, erect a perpendicular and extend it until it cuts the inclined line O-F. The length B-F will be the tangent of the angle and will measure 1.73205 inches. From the opposite end of the 90 degree arc draw the horizontal line C-E parallel to the base line. The length C-E will represent the cotangent of the angle and will equal .57735 of an inch in length. These values are constant for a one inch radius and 60 degree angle. Other functions than the four above-mentioned may be used in trigonometry, but for all practical purposes these four are ample for all shop calculations.

For the students' convenience we have reproduced a table with the constants of the various functions from 1 to 90 degrees, by variation of half degrees, but for greater accuracy we would recommend the use of a table where the values of every minute are given.

Using letters shown in the functional sketch, the following rules may be used for the solution of right triangles, examples here given being for a radius (hypotenuse) of one inch, and 60 degree angle. Suppose we have three holes to locate in a die block and the dimensions given are shown in the sketch; what is the exact centre distance between the other holes?



It will be seen that the centre lines of the holes form a right triangle A-B-C, and from the rules given the solution for the distance B-C would be the tangent for a 25 degree angle, this being .46631.

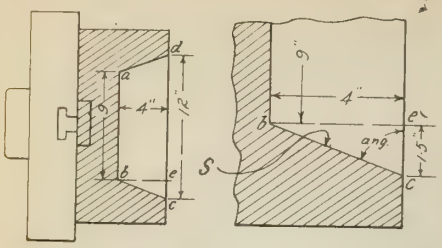
$$\text{Side Opp} = \text{Side Adj.} \times \text{tangent.}$$
$$\text{B-C} = 2.25 \times .46631 = 1.049 \text{ in}$$

For the length A-C the solution would be:

$$\text{Hypot} = \frac{\text{Side adj.}}{\text{Cosine}} = \frac{2.25}{.90631} = 2.4826 \text{ in}$$

In the construction of a forming die as shown in the sketch below, it is desired to know the angle at which to set the compound rest to turn the surface

S, and also the length of the tapered portion.



The tapered length may be found by extracting the square root of the sum of the squares of the two sides, or

$$\sqrt{4^2 + 1.5^2} = \sqrt{16 + 2.25} = \sqrt{18.25} = 4.272 \text{ in}$$

To find the inclination of the compound rest, or the angle B-C-E, we can use the rule:

$$\text{Tan} = \frac{\text{Side Opp.}}{\text{Side Adj}} = \frac{4}{1.5} = 2.6666$$

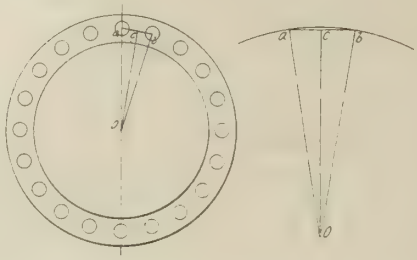
This value lies between the constants given for the tangent of 69 degrees and 26 minutes, and the tangent of 69 degrees and 27 minutes, so for close enough work a setting can be made of either one of these angles.

In a previous lesson on proportion it was shown how the height of a chimney or other elevation could be calculated, but greater accuracy could be obtained by the use of "trig." The sketch below shows the method of procedure:

Suppose by the use of the surveyor's sextant that a sight is obtained to the top of the stack at an angle of 28 degrees, when at a distance of 100 feet from the base of the chimney, the diameters of the top and bottom being as shown. The height is calculated by the rule:

$$\text{Side Opp} = \text{Side Adj} \times \tan = 102 \times .53171 = 54.23'$$

Twenty equally spaced holes are required to be located on a circle 18 inches in diameter; what must be the spread of the trammel points to step off the hole centres?

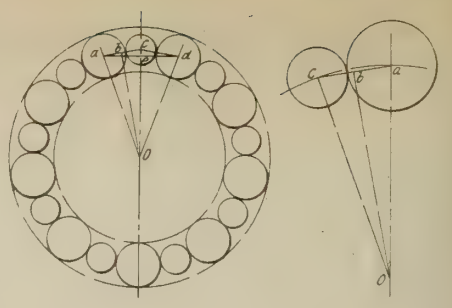


As there are 20 holes on the circle it is seen that the angle formed by two adjoining radii will be $360 \div 20 = 18$ degrees, and the angle C-O-B will be one-half of this, or 9 degrees. The chord A-B is the length required, and this is found by solving the right triangle O-C-B. With the centre angle and the hypotenuse known the short side C-B may be calculated by the rule:

$$\text{Side Opp.} = \text{Hypot} \times \text{sine} =$$
$$9 \times .15643 = 1.40787$$

This, then, is the length of half the chord, so that the trammel distance will be double this, or 2.81574.

Suppose we are making a ball race in which a series of nine ⅜ inch and nine ¼ inch balls are to be used, all the balls to touch those adjoining, what will be the mean diameter of the race?



The above sketch illustrates a general layout of the race and the factors necessary for determining the desired diameters. The angle formed by the central radii of any two adjoining balls will be $360 \div 18 = 20$ degrees, and the centre angle of the right triangle O-B-C- will be 10 degrees. The mean radius of the ball race will be equal to the hypotenuse of the right triangle. The rule to apply would be:

$$\text{Hypot} = \frac{\text{Side Opp}}{\text{Sine}} = \frac{3.125}{.17365} = 1.8 \text{ in}$$

Therefore, the mean diameter of the ball race would be $1.8 \times 2 = 3.6$ inches.

In a certain sheet metal-working machine a head is advanced by the action of a special cam shaft that revolves through the centre of the head. Each revolution of the shaft advanced the head ½ inch, and this movement takes place in about 1-10 of a revolution; the head being stationary through the remaining 9-10. A sectional view of the arrangement is shown below.

°	′	Cosine	Sine	Cotan	Tan	°	′

The cam strip is fitted into the shaft and has a width of 1⅛ inch. The axial distance between the cam slots must equal that of the parallel grooves in the shaft, but in shaping or milling these the cross movement of the table will necessarily be less. It is required to find the table movement of the machine when cutting the slots in the strip, and likewise the angle at which the work must rest in relation to the run of the strip. The rule to apply and the solution will be:

$$\text{Tan} = \frac{\text{Side Opp}}{\text{Side Adj}} = \frac{.5}{1.125} = .44444$$

This value corresponds to an angle of 23 degrees and 58 minutes, or slightly less than 24 degrees, and this will be the inclination of the table. The cross movement of the table for each operation will be found by the rule:

$$\text{Side Adj} = \text{Hypot} \times \text{cosine} = .5 \times .91378 = .456$$

To secure greater accuracy from the table here shown proceed as follows: Suppose the sine of the angle, after the usual calculations, comes to .57840. It will be seen that this value falls between that shown for 35 degrees and that for 35 degrees 30 minutes. Find the difference between the sines of the two known angles (to the left below) and also the difference between the smaller angle and the required sine (shown to the right).

.58070	.57940
.57358	.57358
.00712	.00482

The number of minutes can now be found by proportion, the value .00712 equalling 30 minutes, the difference in the table values. Thus:

$$.00482 : .00712 = x : 30$$

$$x = \frac{.00482 \times 30}{.00712} = 20.3$$

The angle corresponding to the sine .57840 will then be 35 degrees 20 minutes and 18 seconds.

History of the Principles of Centrifugal Pumps

The Rees-Ro-Turbo Type of Pump is Herein Described, and Various Illustrations Are Given of Interesting Portions of This Class of Pump—A Reading Will Prove Worth While.

By J. H. MOORE, Associate Editor Canadian Machinery

BEFORE going into the construction of this type of pump, let us go back quite a few years, and see where first the idea of centrifugal pumps appeared.

Something over two hundred years ago the centrifugal pump was invented by Demesne Papin in Hess, Germany. Little seems to have been done with it in a practical way for a long period. It first appeared in this country in 1818, and was known as the Massachusetts Pump. Gradual improvements were made in its design by Andrews in 1839, Bessemer in 1845, Appolod in 1848, and Gwyne in 1851. The development was slow and until within the last ten years was not considered seriously by many engineers, except for large capacities and for extremely low heads.

No doubt the delayed development was largely due to the fact that to get the best results from a centrifugal pump, impellers should be of small diameter running at high speed, but until the advent of the electric motor and steam turbine there was no means of driving centrifugal pumps at the necessary speed except through belting of gearing with their inseparable difficulties and losses in transmission, which neutralized the advantages aimed at in the pumps. With the introduction of electric motors and steam turbines high efficiencies became possible, and for high lifts the old arrangement of impellers in series was revised and the centrifugal pump became a strong competitor of the plunger pump for conditions which used to be looked upon as only suitable for reciprocating pumps.

Perhaps the defect which has been the most difficult to overcome and which has decided the buyer in many cases against this type of pump, has been the fact that it would work at its best only at the exact head for which it was designed, the reason for this being that the blades of the impeller were shaped so as to pass a certain amount of water with the minimum frictional loss, due to cavitation; but if the head against which the centrifugal pump is working reduces, a greatly increased volume of water passes and the impeller then becomes unsuitable for the increased speed of the water through it and begins to act as a water brake, thus creating an overload on the driving machine.

These conditions were well-known and until the introduction of RoTURBo by Rees of Wolverhampton, England, in 1907, it was attempted to overcome them by designing the impeller with blades bent rearwards so as to reduce the break effect. This necessitated increase in the speed of the impeller to compensate for the slip of the water, and beyond a certain amount of recurvature the capacity of the pump is very greatly reduced and the internal friction of the impeller increased with consequent loss of head at anything but a restricted range of service.

True, turbine pumps are of such comparatively recent development that the general public and, in fact, many engineers have not been sufficiently well informed upon the subject to distinguish between a high grade turbine pump and an ordinary commercial centrifugal pump. The Rees RoTURBo pump represents the most advanced in true turbine pumps.

Venturi Pipe

What is know as the Venturi principle is embodied in a specially shaped contraction in a water pipe having an abrupt nozzle where the water enters the construction, and a gradually expanding taper piece after the water has passed the contraction. The result of this is that the water under pressure in the pipe is forced through the neck at a high speed, and in doing so it loses its pressure, in the inverse ratio to which it gains velocity, so much so that the whole pressure can be annulled in the neck if the contraction is sufficient and an actual vacuum can be created. When the water enters the expanding pipe the speed of the same is slowed down again, due to the increasing diameter, and as the speed is lost the water regains its pressure. The Venturi pipe, therefore, is a hydraulic transformer, with a double transformation, converting from pressure into velocity and the velocity back again into pressure, and without much loss.

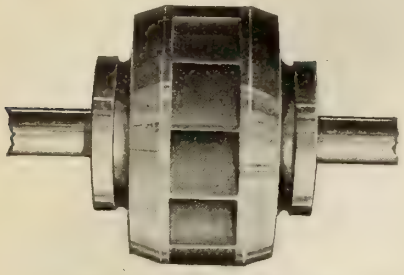
The special shape of the Venturi pipe is because a very abrupt contraction will convert pressure into velocity, but a carefully designed expanding piece of about 10 or 12 degrees expansion is necessary to attain the second conversion, because if the expansion is abrupt the water leaves the sides and the head (instead of being regained) is lost in friction and eddies.

In the ordinary centrifugal pump with an open rim impeller, the object is to pick up the water in the eye of the pump and get up a high peripheral velocity as of the water as it leaves the impeller and convert this velocity into pressure in the expanding channels of the pump casing; a very difficult and inefficient conversion.

These expanding channels are the exact counterpart of the expanding part of a Venturi transformer, but the contracting part of the Venturi transformer was not previously used in centrifugal pumps until what is known as the Rees RoTURBo Pressure Drum replaced the ordinary impeller. The pressure drum is a water chamber of large capacity, in which, by centrifugal force, a pressure is accumulated; the water being flung against the

rim by the revolution of the drum and generating a hydraulic pressure inside of the drum. The water is allowed to escape through abruptly contracted openings in the rim, precisely in the same manner as the contracting part of the Venturi pipe.

These openings, or nozzles, are pointed backward, and as the water escapes from them the jets of water have a turbine effect and give self regulation or a



SINGLE-STAGE IMPELLER.

reduction of power when the head is reduced and a larger volume than the normal passes through the pump. The contraction of the openings is such that only 25% of the initial pressure is converted into velocity. That is to say, the water going through the nozzles at normal duty has a pressure of 75 per cent. and a velocity equivalent to 25 per cent. only. This velocity is picked up again in the expanding channels of the pump casing, so as to make the total pressure of the water being delivered from the pump equal to the 100% originally intended, but by this arrangement only 25% of the head is picked up in the expanding part, instead of the 100% as in the ordinary pump. As the expanding part of the Venturi transformer is the most difficult to design, and the efficiency of the same depends entirely upon the accurateness with which this part is designed, it will readily be seen why a pump of this type leads in the matter of efficiency.

General Principles

The design of the pump is exceedingly simple, comprising a single or a series of pressure drums (the number depending on the nature of its work), rotating inside a cast-iron casing at a moderately high speed. These revolving pressure drums are mounted on a central shaft supported in bearings. There are no moving parts in contact, except at the bearings, and the whole of the internal arrangements are such that the pump is in hydraulic balance and free from any lateral end pressure on the shaft. The main bearings are external and oil ring lubricated, and packing arrangements are exceedingly simple.

When running the water gravitates or is drawn into the eye of a revolving pressure drum where its speed is slow relative thereto, the water being carried round by the revolving partitions. A pressure is created in the revolving drum by centrifugal action of rotation, and the capacity of the chamber being large the water slowly moves towards the periphery, where there are a number of short nozzles curved in a direction opposite to the direction of rotation. These nozzles convert a portion of the pressure into velocity, and the water passing through them behaves as in a turbine, assisting the rotation of the revolving drum, thereby giving a self-regulating effect. The escaped water still having velocity in the direction of rotation, is passed between stationary diffusion channels which convert the remaining velocity into pressure. A considerable space is left between the revolving nozzles and the stationary channels, greatly minimizing the effect of any wear and tear.

The Rees RoTURBo Pump is a fully developed and well tried piece of apparatus, thousands having been installed in the last few years in all parts of the world. Experience has shown that in many cases where RoTURBo Pumps have been running uninterruptedly for several years with unusually dirty and gritty water, there has been no scouring or wearing action visible when they were opened up for inspection; hence a permanent efficiency is maintained.

Impeller

The special feature of the pump, which (instead of being built as a flat disc runner with the main object of securing velocity of water in the expanding channels of the fixed casing), is designed in the form of a barrel or pressure chamber, the object aimed at being to secure a constant pressure inside the revolving drum or impeller, equivalent to the height of the lift. The impeller having this large capacity, the water inside as it approaches the rim becomes practically stationary relatively to the impeller, thus eliminating frictional losses and generating a pressure by centrifugal force.

Another interesting feature to note is that the highest efficiency point of the Rees RoTURBo Pump is when the speed of the water issuing from the impeller in a rearward direction is 50% of the peripheral speed of the impeller and this for the same reason that the Pelton wheel gives the highest efficiency when the speed of the buckets is half the speed of the water jet. In fact, the Rees RoTURBo Pump may be looked upon broadly as a reversed Pelton wheel in which the buckets are stationary and a series of nozzles on the rim of the impeller revolve, whilst the ordinary turbine pump with the narrow disc impeller is, of course the reversed vortex turbine.

The Effect of Self-Regulation

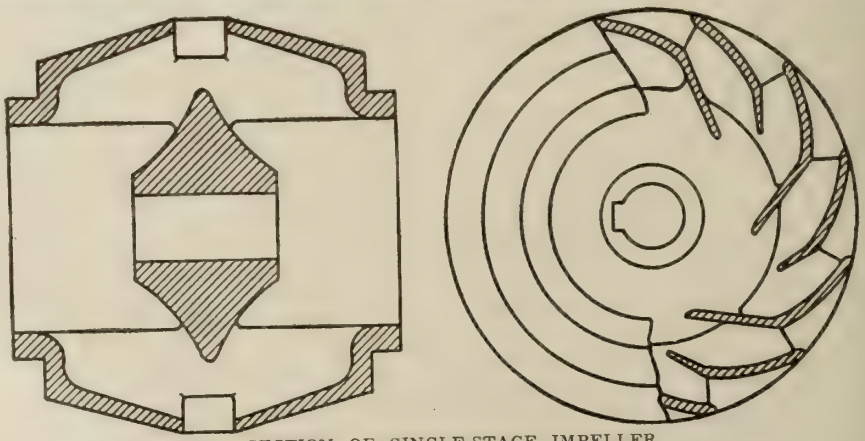
The self-regulating pressure chamber is the equivalent to a pump and a turbine in series, the result being that if the head varies or is reduced below the head for which the pump is designed, there is no overload possible, the turbine rim blades extracting the energy of the increased speed of the water through the impeller, which otherwise would be thrown to waste. It follows, therefore, that the margin of horse power usually allowed on the motor in the ordinary turbine pump for this emergency is unnecessary, it being absolutely impossible for the pump to overload materially the motive power so long as the speed is kept constant, regardless of the head against which the pump is working, or as in the extreme case of a pipe bursting, taking the head off the pump entirely. The value of this feature of the pump in keeping down power costs to the lowest point without the necessity of complicated arrangements for speed variation or cutting out impellers, will at once appeal to the manager or engineer.

With further reference to self-regulation and the turbine effect, it should be noted that the impeller becomes a pump and a turbine in series, with a pressure chamber between the two portions. The pump portion is, therefore, always discharging into a constant pressure, which is the ideal condition for a centrifugal pump, and the turbine is always discharging from a constant pressure, which is the ideal condition for a turbine.

The result of the combination just described is perfect self-regulation with the highest efficiency and, at any head lower than the normal duty, the power taken by the motor is prevented from rising.

Rees RoTURBo Characteristics

When running under a constant speed the Rees RoTURBo Pumps are designed to deliver a certain capacity against a specified head at this speed, and will give a guaranteed efficiency at that point. If required to deliver water at a higher head (and all the following calculations are based on a constant speed),



SECTION OF SINGLE-STAGE IMPELLER.

the pump will deliver against this higher head up to 115% of the designed head. The amount of water delivered will decrease as the head increases above the designed head. and the efficiency will also decrease likewise.

SINGLE-STAGE DIFFUSER.

For instance: At 106% of the designed head the pump will deliver 83% of its capacity, and the efficiency will be 95% of its guaranteed efficiency. In a similar manner: At 108% head, delivery is 73%, efficiency 90%. At 111% head, delivery is 60%, efficiency 80%. At heads above, the capacity and efficiency are not dependable, and the characteristic curves for the pump in question will have to be referred to.

For heads lower than the designed duty, the pump is more stable. For instance: for heads from 100% of the designed head down to 82% designed head, the pump will give an efficiency of 100% of that guaranteed, and the capacity at 82% is 126% of the designed.

At 69% head, the capacity is 140% and the efficiency 93%.

At 65% head, the capacity is 145% and efficiency 90%.

At 52% head, the capacity is 155% and efficiency 80%, etc., down to open valve or no head, at which point the pump will deliver in the neighborhood of 192% of the designed duty.

Due to this flat head and volume curve the efficiency of the pump is flat and varies over a wide range.

From the figures given you will note that it is best that the pump operate at heads lower than that for which it is designed. In fact, never, under any circumstances, would it be advisable for pump to operate under conditions where the head will be higher than that for which it was designed.

It will be noticed that the efficiency of the pump remains at the highest point until the head is reduced as low as 82% of the designed head and the capacity has increased to 125%. The pump can operate very satisfactorily down to heads as low as 40% of the designed head, and at this point the efficiency will be 60% of that guarantee, and the capacity will be approximately 160% of that for which it was designed.

A fact which should be remembered is that the volume increases directly as the speed; i.e., if the speed is doubled the volume will be doubled, and at the same time the head will vary directly as the square of the speed, and the head will be quadrupled, and likewise the power will be increased in direct proportion as the curve of the speed, or as the speed doubles the power will increase as the cube of 2 or 8.

Prof. Zowski's Report on Rees RoTURBo Pumps

The following technical report of Prof. Zowski, of the University of Michigan, sets forth clearly the principles involved in the RoTURBo Pump, and will be found of interest. The accompanying curves and test cards should be of assistance in discussing the subject with consulting engineers and others.

The new hydraulic principle embodied in the Rees RoTURBo Pump is that the impeller is used to create pressure head directly, whereas in all other centrifugal pumps the impeller imparts to the water practically speed energy only, leaving it to the diffusor to turn this speed energy into pressure head, which is always a very inefficient transformation.

A chamber of relatively large volume makes up the major part of this casing. A great volume of water is dragging along, and being exposed to the centrifugal force created by rotation is converted into a sort of accumulator which feeds the discharge nozzles and is itself fed by the suction pipe.

The speed of flow in the chamber is very small and its effect upon the pressure head which is caused by rotation is, therefore, very slight. Consequently, we may vary the discharge considerably without changing the pressure conditions in the impeller to any material extent. The variations in the discharge will only change the pressure at the entrance into the diffusor, and this produces the varying pressure differences which are, of course, necessary, if different quantities of water are to pass through the same passage area.

The fact that the speed of flow in the impeller is very small, means also that the theoretical power of the pump is practically dependent only on the pressure head created in the chamber, and therefore, equally independent of the discharge as the same.

If we now succeed in designing a pump in which also the efficiency will be independent of the discharge, then it is self-evident that the variations in the discharge will not affect much the actual power which is required to drive the pump. In the Rees Pump this condition is fulfilled for the following reasons:

1st. Because the speed of flow is very small, the hydraulic loss of the impeller will be very slight as compared with the other hydraulic losses of the whole pump, and changes of speed flow caused by varying the discharge can, therefore, not affect much the total efficiency.

2nd. The impeller nozzles act as turbine buckets, doing useful mechanical work by deviating the discharging water streams, and thus creating the S.C. force of reaction pressing against the buckets in the direction of rotation. This mechanical work increases with increasing discharge, and therefore, neutralizes to some extent the increase of hydraulic losses which takes place when the quantity discharged is increasing.

On the basis of what has been stated

MUTI-STAGE DIFFUSER.

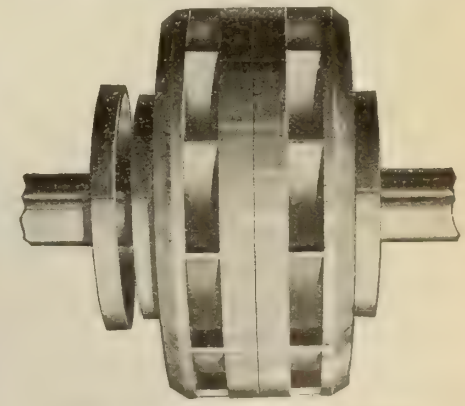
above, the following characteristics may, theoretically, be expected from the Rees Pump:

1st. A flat power curve with varying discharge.

2nd. A flat efficiency curve with varying discharge.

3rd. A total efficiency which must be at least as good as that of any other centrifugal pump, and which, on account of the relatively small velocities which flow through the impeller chamber, may be expected to be even better, if both are designed and built with the same amount of care and precision.

It cannot be the purpose of this report to enumerate the various instances in which this pump may be used to a greater advantage than the other centrifugal pumps, but this seems to be quite certain that the pump is ideally fitted to all services where the operation conditions are variable. Further, the peculiar construction of the impeller makes it relatively easy to use the pump as a wet compressor or as a vacuum pump, as it is a simple matter to admit the air



MULTI-STAGE B TYPE IMPELLER.

or exhaust steam into the wide impeller chamber, and then to compress or mix it with the water in the impeller.

S. J. ZOWSKI.

On all pumps the casing is split horizontally so that the pump can be opened

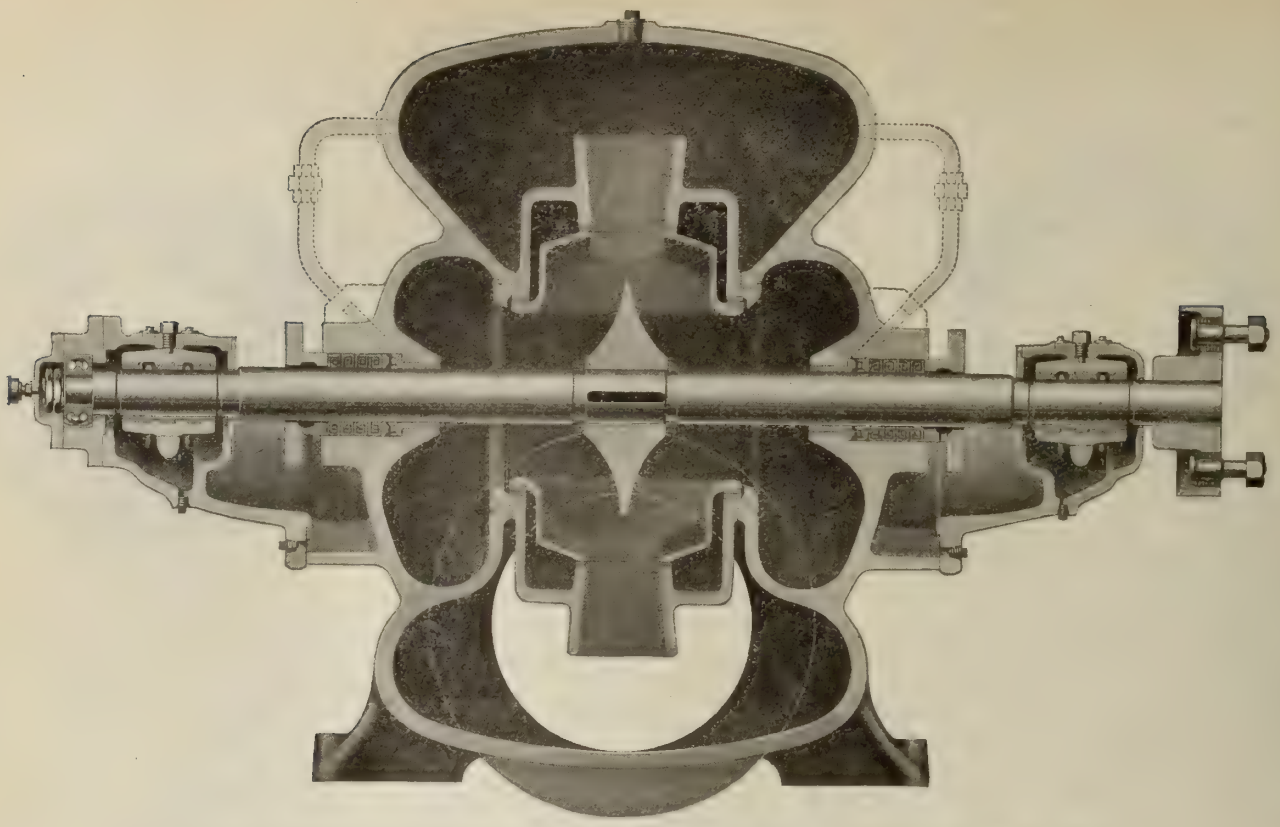


FIG. 1.—C. W. TYPE SINGLE-STAGE PATENT PRESSURE CHAMBER PUMP.—SECTIONAL VIEW.

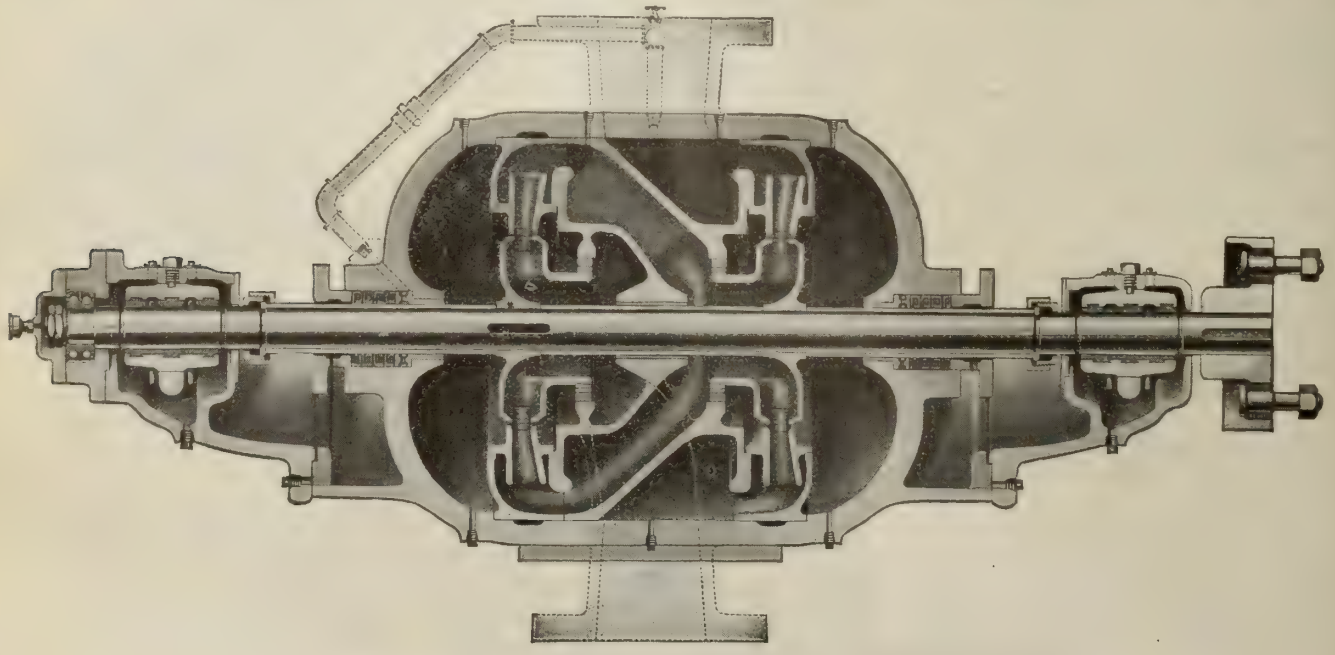
out and the internal parts examined by simply removing the top half of the casing.

It is very advisable to have both the branches, that is to say, the suction and discharge openings, in the bottom half of the casing, so that the top half can be removed without disturbing the branch connections. The standard arrangement is with both the suction and discharge branches horizontal and below the centre line of the pump. The suction branch can be made vertical if specially required. The horizontal suction branch is, however, preferred. The standard arrangement is with the discharge branch on the right hand side looking on the thrust end of the pump, but it is equally satisfactory to have it on the left hand side.

This pump may be made with either one or two main bearings. When the prime mover is supplied by another firm our practice is to fit two main bearings in all cases, but when the prime mover is supplied by ourselves, one main bearing is sufficient in the case of reciprocating engine drive and on small units with turbine drives up to moderate speeds; but in the case of high speed turbine drives (above 2200 R.P.M.) or units absorbing more than 50 H.P., two bearings should be supplied. With two main bearings a flexible coupling is used, but with only one main bearing a solid coupling is required. A brief description of the various types is given below:

C. W. Type

These pumps may be used for heads up to 120 feet, when the impeller is made of cast iron; double that head when it is made of bronze. It is not usually good

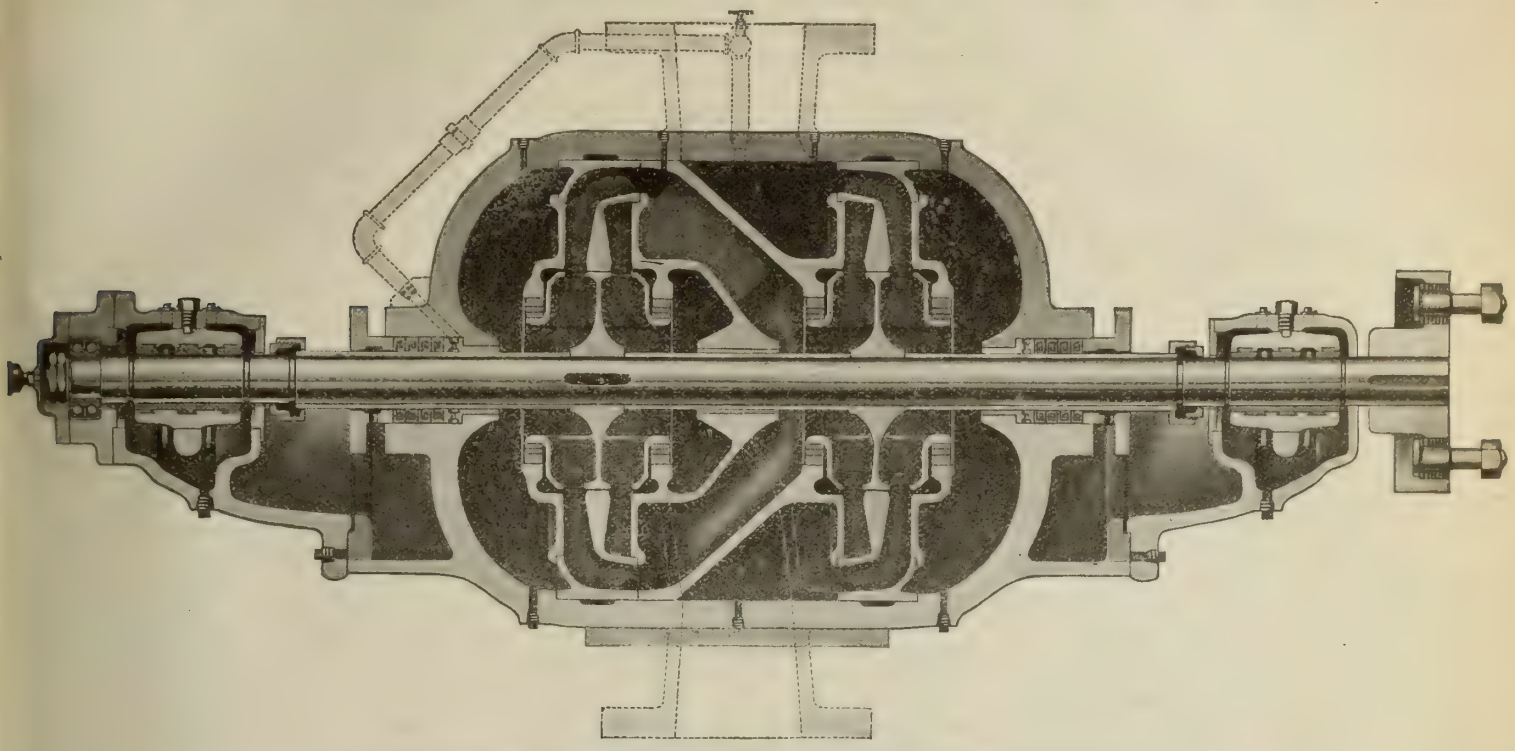


S2.—TWO-STAGE PATENT PRESSURE CHAMBER PUMP.—SECTIONAL VIEW.

practice to exceed 180 feet on a single-stage C. W. pump, unless it is of considerable capacity. Lubrication is by one or two oil rings, running over the shaft and dipping into a large reservoir beneath. This bracket also contains a

furnished, thus providing a bearing on each side of the pulley. Lubrication is by ring oiling. The efficiency of this pump will range from approximately 40% on a very small pump to 80% on a large one, depending entirely on the

fore the capacity of an equivalent size S-2 impeller is only one-half that of a C.W. type of pump of the same diameter, the capacity limit of the impeller being based on the velocity of water through the eye. The impellers in these pumps,



B2.—MULTI-STAGE PATENT PRESSURE CHAMBER PUMP.—SECTIONAL VIEW.

two way ball thrust bearing, which acts as a centreing block for the impeller, keeping the nozzles in line with the diverging channel. In special cases the branches may be located at almost any position on the periphery of the casing to suit the convenience of the customer; but this should be avoided whenever possible, as it means special attention in designing and will probably entail delays in shipment.

The base plate is of cast iron, usually in one piece of the heavy boxed ribbed type, extended to receive the driver. For belt drive, two pedestal bearings are

fitness of the pump in question to the service demanded of it. Efficiencies obtainable are found for any given conditions from the efficiency charts. In practice the best efficiencies are obtained with heads varying from 40 to 140 feet.

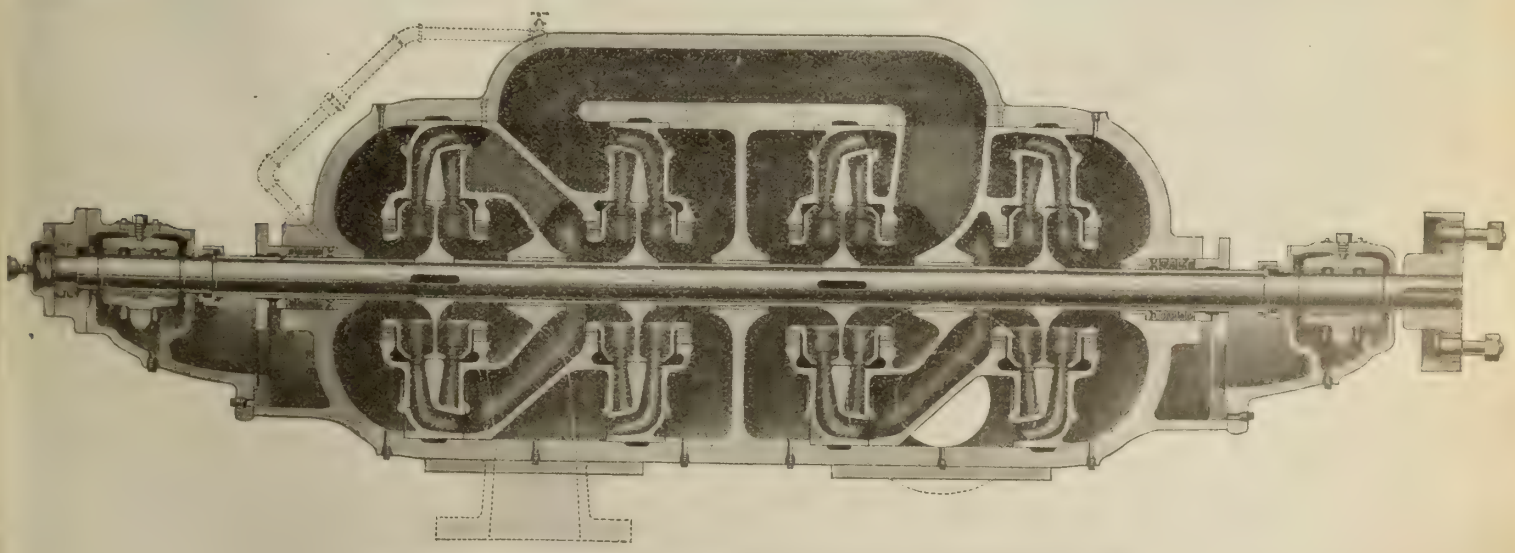
S-2 Pump

This consists of two single stage, single impeller, single suction pumps, mounted on one shaft, and placed in one casing; in reality, this is two single stage pumps in one casing. The impeller differs from that employed in the C.W. Pump in that the water enters on one side or through one eye only, and there-

when mounted on the shaft face to face, are so arranged that water under pressure flows to the back of them, thus hydraulically balancing them with regard to end pressure. The diffusors of these pumps are two in number, and are of the straight way type similar internally to those used on the C.W Pump. What has already been said about number and type of bearings for previous pump, is also applicable to the S-2 Pump.

B Type Pump

This type of pump is one which is particularly well adapted for exacting service. It has many advantages over



B4.—EIGHT-STAGE PATENT PRESSURE CHAMBER PUMP.—SECTIONAL VIEW.

the ordinary centrifugal pump besides the special feature of the capacity chambers. It is multi-stage built in multiples of four, and not otherwise. The impeller is of the two stage type, each impeller having two stages back to back with an eye on both sides. This is a mechanical advantage in that it shortens the length of the pump, and consequently the distance between bearings. The arrangement of the stages in multiples of four only, is clearly explained by reference to the method of obtaining hydraulic balance. This hydraulic balance is not only theoretically perfect but is actually so. This can easily be proven by the fact that on pumps up to 16 stages and more, a standard type of ball thrust bearing is used for the centreing block instead of the usual type of collar, water cooled marine thrust bearing, used by other pump manufacturers to take up end thrust. The end thrust experienced in RoTURBo Pumps is practically negligible. The purpose of the ball thrust used is to keep the impeller in line with the diffusors. The compactness of the pumps is further facilitated by the use of cross over diffusors. These diffusors are two combined in one, and cross the water from one stage of the pump to the next, and in this way (the water being crossed in a correct manner from one stage to the next) the pump is balanced with reference to end pressure. B types of pumps usually contain two bearings, both external to the casing, supported in brackets from each end of the pump. These are the same as those used in the other pumps, and are lubricated by means of two rings to each bearing dipping into a large reservoir of oil beneath, which has an overflow and drain. Above each stage of a B type pump is a relief or pet cock, its purpose being to relieve the entrapped air. B & S types of pumps have bronze covered shaft; the other type of pumps have steel shaft unless bronze is specified, which will be special and for which an extra charge will be made. B type pumps are used for heads from 100 to 1,600 feet. Their efficiencies are found from the efficiency charts. Given the volume and head per stage on the pump the best efficiencies are obtained with heads of from 40 to 140 feet per stage.

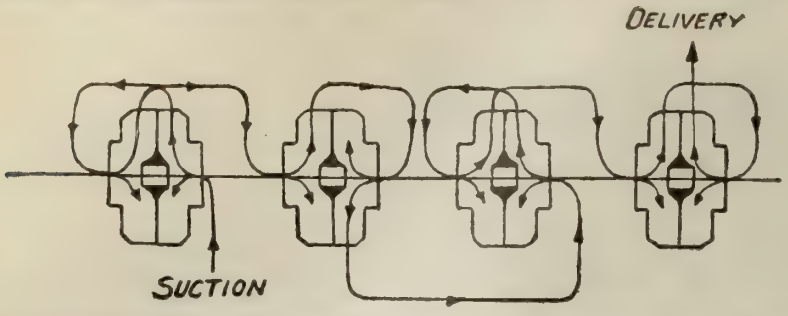


DIAGRAM SHOWING FLOW AND HYDRAULIC BALANCE OF A B4 EIGHT-STAGE PUMP.

The makers of these pumps claim the following features and advantages derived from their pumps, namely that:

1. A drooping power curve, i.e., a power curve which rises not more than 10% as the volume is increased beyond the designed duty point and falls away as the volume is still further increased, thus making it impossible to impose an overload on the motor or turbine which may be used for drive.

2. High and permanent efficiency maintained over a very wide range of heads and volumes, i.e., a flat efficiency curve.

3. A head and volume curve which goes out to approximately 200% of the volume at the designed duty point when delivering against no head, in other words, maximum increase in volume at reduced heads. This is a great advantage for many purposes.

4. Owing to the low water velocity through the impeller and stationary passages, there is almost complete freedom from wear, even when pumping gritty water. This forms a marked contrast to the ordinary centrifugal pump, where facilities have to be provided for the renewal of blade tips and other parts, due to the excessive erosion. With much wear, of course, in pumps of such construction, the efficiency falls rapidly.

5. An outstanding feature of the Rees RoTURBo Pump is that both single and multi-stage pumps are in perfect hydraulic balance, thus eliminating the expensive marine thrust bearings and balancing pistons which are always liable to wear and give trouble as soon as the clearances of same become worn through pumping gritty water. A small two-way ball thrust is usually fitted, the function of which is merely that of a centreing block to maintain alignment between the impeller and the diffusors.

6. The strong and rugged design of the impeller, diffusors and casing insures complete freedom from noise and vibration.

7. The pump is especially suitable for use with liquid of a gritty or viscous nature, owing to the low velocity through the impeller and casing, and has been largely used for pumping thick oil, sugar, liquids, etc.

8. From a mechanical point of view the pump is fully standardized and all wearing parts are easily replaceable, being made to gauge and kept in stock, thus permitting quick shipments on receipts of orders for repairs. The design of the pump is specially adapted for a wide range of duties with a given pattern by small alterations, thus reducing the number of patterns carried to a minimum and enabling us to completely standardize all parts.

From the foregoing history, and detailed description of these pumps, it will be noted that efficiency is a very strong feature. To class them as a centrifugal pump only is a huge mistake, for they combine, as the trade-mark RoTURBo infers, a rotary, turbine effect, and not simply a centrifugal pump effect. Perhaps the most interesting portion of this article follows, namely, that these pumps are now being built in Canada, by the Goldie McCulloch Co., Limited, of Galt, Ont., who have secured the sole rights for these pumps in the Dominion of Canada. For the past seventy years this firm has specialized in the production of high grade power equipment, so it is hardly necessary to mention that they are in splendid shape to manufacture work of this kind. The various photographs accompanying this article can be easily understood from the descriptive matter in the body of the article, and to aid readers to pick out the various types, titles are placed under each photograph. This firm when speaking with the representative of CANADIAN MACHINERY mentioned that they were only too pleased to answer enquiries relative to these pumps, and that such information in catalogue form was to be had for the asking.

A. R. Roberts, formerly if Burns & Roberts, Ltd., Toronto has discontinued his connection with the firm, and has opened an office at 201 Bank of Hamilton Building, Toronto. He will deal in new and used machinery, contractors' railway and power plant equipment.

ACKNOWLEDGMENT

The following firms were good enough to supply us with the photographs, etc., illustrating article on shop transportation in our last issue:—

Herbert Morris Crane Works, Niagara Falls, Ont.

Equipment Mfg. Co., Cleveland, Ohio (Griswold & Hammond are their advertising representatives, Cleveland, Ohio).

Jeffery Mfg. Co., Columbus, Ohio.

Northern Crane Works, Walkerville, Ont.

General Electric Co., Schenectady, N.Y.

Curtis Pneumatic Machinery Co., St. Louis, Mo.

The Electric Storage Battery Co., Philadelphia, Pa.

The Cowan Truck Co., Holyoke, Mass.

The Lamson Co., Boston, Mass., (Jones & Glassco are their advertising representatives, Montreal, Canada.)

Cheese Factory Boiler Explodes at Joyceville

Little Village Near Kingston is Scene of Disastrous Explosion—Boiler Ruptures Along Longitudinal Seam, Which Was Badly Corroded—No Inspection Had Been Made on This Boiler Since Installation

T. H. FENNER, Associate Editor Canadian Machinery

THE question of the adequate and regular inspection of steam boilers is once more brought to the public mind in a way that defies evasion. Once again a boiler in an industrial plant has exploded without a minute's warning, leaving in its trail a wrecked building, and worse still, destroying two human lives. Both the victims were young men, with many years of life in front of them under ordinary circumstances.

The boiler in question was in use at the cheese factory of Thomas Anglin, of Joyceville, and was of the horizontal return tubular type, about 38 inches diameter. It was similar to most of the cheese factory boilers, of which there are no less than one thousand and forty, known and listed in the Factory Inspection Department. There are probably many more than this in use, for it is a difficult matter to keep track of these boilers. Under the Factory Act, steam boilers in use on farms, or for general agricultural purposes, are exempt from inspection. Cheese factory boilers were at one time also exempted, but for some years past they have been brought within the law.

The original thickness of the plate was ¼ inch, and the boiler was made up of two sheets, the longitudinal seam being single riveted. We have no particulars of the pitch, but with a joint of this kind the percentage of strength to the solid is approximately 50 to 54. On this assumption the resistance of the shell to internal bursting force would be, with a factor safety of 5, about 70 lbs. if made of steel. This, if the boiler was in good condition, which it was not.

Some interesting statements were made at the coroners' inquest relative to the operation of the boiler. It had been installed in 1915, having previously been in operation for some time. The owner was supposed to have notified the Steam Boiler Department at that time, but presumably was not aware of this. It was not until two years after that he received a circular from the Factory Inspection Department, notifying him that an inspection was necessary. He then called in a local firm, who made a repair by patching the boiler. The repair people undertook to notify the Inspection Department, and apparently did so. The inspection was not made for reasons given later in this article. The owner thereupon let things slide, evidently believing it was no affair of his. He continued using the boiler, and finding that the safety valve opened at about 40 lbs. pressure, hung some more weights on the lever, to bring the pressure up to 80 lbs. It was stated that the boiler actually blew off at 100 lbs. per square inch. At the time of the explosion, the pressure was stated by Edward Gallery, the cheesemaker, to be between 80 and 100 lbs.

This man was presumably the operator of the boiler. He had received some instruction in boiler operation while taking his course for cheesemaking. He was not aware that any inspection was necessary, and stated that he never heard of inspections being made in other cheese factories.

Here we have the two men most interested in the boiler, one the owner and one the operator. The owner knew that the boiler should be inspected, but, when the inspection did not materialize, took no steps to find out why. The other man had no idea that the boiler needed inspection, and cheerfully went on operating without the slightest conception of the danger he was running. When the catastrophe took place, it was two men who were not even employed at the factory who were killed. There is an instance of fate's irony.

The provincial inspector, who made an examination of the remains of the boiler after the accident, found evidence of deep corrosion on the seam where the rupture took place. The plate was grooved until a bare one-sixteenth of an inch thick. He stated that the boiler was poorly built, and when new would have been good for only 54 lbs. per square inch. If it had been inspected by him he would have condemned it, or allowed only 15 lbs. per square inch.

Two weights were found which had been on the safety valve lever. Had they been at the end of the lever it would have required a steam pressure of 200 lbs. per square inch to raise the valve. The steam gauge, never having been tested, may have been considerably out, and probably was.

Here is a case where, had the inspection been made, the accident would have been prevented. The reason given for not making the inspection is a shortage of inspectors, there being only six for the whole province of Ontario. In the case of cheese factory boilers, the difficulty of inspection is enhanced by the out-of-the-way localities they are usually placed in. This makes the inspection a matter of a whole day in some cases, and when the number of boilers are considered, it is quite to be understood that some of them are missed. There are many owners of boilers who take no interest in the safety of their property, either through ignorance, or a desire to save the fees. There is a great need of a means to enforce the laws already in existence. In this connection a good plan has been suggested. It is that instead of having the inspectors all atttached o the central office, the province should be divided into districts, with a resident inspector in each. This inspector would know the district and everybody in it, and the possibility of a boiler being operated without inspection would be reduced to a minimum.

It would also prevent a thing that frequently happens now. A man has a boiler on his farm which comes under the agricultural classification and is, therefore, exempt from taxation. He takes up cheese manufacturing, or starts a sawmill, and the boiler is then, of course, in commercial use, and liable to inspection. If the owner himself does not notify the Factory Department of the change, it is quite probable that under the existing conditions he may operate it for one or two years before anything is known about it. Resident inspectors would know of a case of this sort immediately.

The Case of the Farmer's Boiler

This brings us to another consideration. Why should any steam boiler be exempt from inspection merely because it is not used for commercial purposes? A farmer who uses a threshing engine, or steam tractor, is not compelled to have it inspected.

The viewpoint of the Legislature is presumably that a man using a boiler on his own land for what may be reckoned as purely domestic purposes, should not be bothered with inconvenience of Government supervision.

Speaking generally, the less the Government interferes with private enterprise, the better; but here is a case where it is in the interest of the man himself to interfere. The law puts effective checks in the way of the purchaser of poison, even if only to kill vermin, or a dog who has had his day. It should do the same with such a highly dangerous instrument as a steam boiler.

There is a very wide spread fallacy among small steam users that because a boiler is comparatively small and operating at low pressure it can't do much damage anyway. They are partly right. A 30 inch diameter boiler operating at 100 lbs. pressure is not so dangerous as a 60 inch boiler operating at 50 lbs. pressure, but it is dangerous enough. The explosive force of a boiler lies not in the pressure it carries, but in the heat energy contained in the water. The greater the weight of water, the greater the damage that will be done. This

Interesting Thermit Weld to Crank Shaft

By J. R. RODGERS

THERMIT welding is now recognized as a most effective and economic means of repairs to equipment and broken parts of machinery, particularly of the heavier variety where great difficulty would be experienced with the other methods of repair. The illustrations on this page show the various stages in a repair to a two throw crankshaft taken from a high speed paper machine in one of the large pulp and paper mills. The estimated loss to the plant by the break of this shaft was approximately $200 per hour, so it was essential that operations be delayed as brief a period as possible. The shaft was removed from the machine and expressed to Montreal, where the St. Lawrence Welding Co. effected the repair by thermit welding. The time required to make the weld, after the shaft was received in the shop, was about 30 hours. This included the alignment of the shaft and clamping in position on the floor plate, the construction of the mold, the pre-heating period of 7 hours, and the actual weld, the latter only occupying a few seconds.

In setting up work of this character it is always necessary to allow for the shrinkage of the metal as the weld cools off. The two parts being completely separated by the break and the portion cut away, there is no lengthening of the shaft during the pre-heating period, so that the contraction after welding must be carefully calculated when setting up the work. After the repair it was found that the error of alignment and concentricity was less than 1/200 of an inch. The machining was completed by the Hydraulic Machinery Company in about 20 hours, and the shaft returned to the mill in less than four days from the time of the break, so that the operations were resumed at the mill with the minimum degree of shutdown. The shaft was over 14 feet in length with diameters ranging from 6 to 8 inches, cranks being 5¼ inches in diameter. The break took place close to the web of one of the cranks, as seen in the cuts herewith.

TICKLISH TUNNELING UNDER THE EAST RIVER

A very interesting bit of tunneling was recently done on the 14th Street tube under the East River, New York. The heading was being run in rock, and at one point test holes showed a thickness of only eight inches of sound dry rock above the line along which the top of the tunnel was to run. As the tunnel was being driven without the use of compressed air it was decided to drop the upper heading four feet until this thin cover of rock was passed. The cast iron lining was set in place at each side of this section and then the rock was removed very carefully by using a great many holes, each loaded with about one-eighth of a stick of dynamite. As each bit of rock was removed to the arch the tunnel lining was set in place. By this means the dangerous section was tunneled without breaking through the thin shell.

Commercial developments by air are rapidly taking a tangible form. This is shown in the active interest taken by the aviation department of Vickers Limited, of England, and the request that has been forwarded to this company by the Chamber of Commerce and the Aero Club of Atlantic City, N.J., to seriously consider the city as the Atlantic terminal for any commercial route that may be established. It is believed that the American agents of Vickers are even now studying the advisability of making this port the western terminus of a proposed transatlantic route for air tourists.

THE ZEUS ARC WELDER

ELECTRIC arc welding of the past has been thought of in the light of large cumbersome installation of considerable cost. It has further been understood that since it consists of a motor generator set entailing moving parts, there might be some difficulty in connection with its operation from time to time. It has always been understood to be inefficient on cast iron and in connection with overhead welding.

This new arc welder, manufactured by the Gibb Instrument Company, of Detroit, Michigan, is built of an entirely different type. The motor generator set with its disadvantages of bulk and moving parts, has been supplanted by a simple transformer with no moving parts, and like all transformers with nothing to get out of order. It has been found that the current consumption is from twenty to forty per cent. less than the motor generator type. One big feature is its adaptability to overhead welding, which class of welding has given considerable trouble in the past with the arc welding equipment. It has further been found to be particularly efficient in the welding of cast iron, which has been another difficulty in the way of the unqualified success of the types of the past.

This welder is comparatively small, making it unnecessary to set aside expensive space for its accommodation. Further, because of its convenient size, it is portable.

The "Z E U S" is built on a unit system, whereby a concern may install a 150 ampere machine, and when the work becomes heavier, a duplicate may be connected in parallel with the original machine.

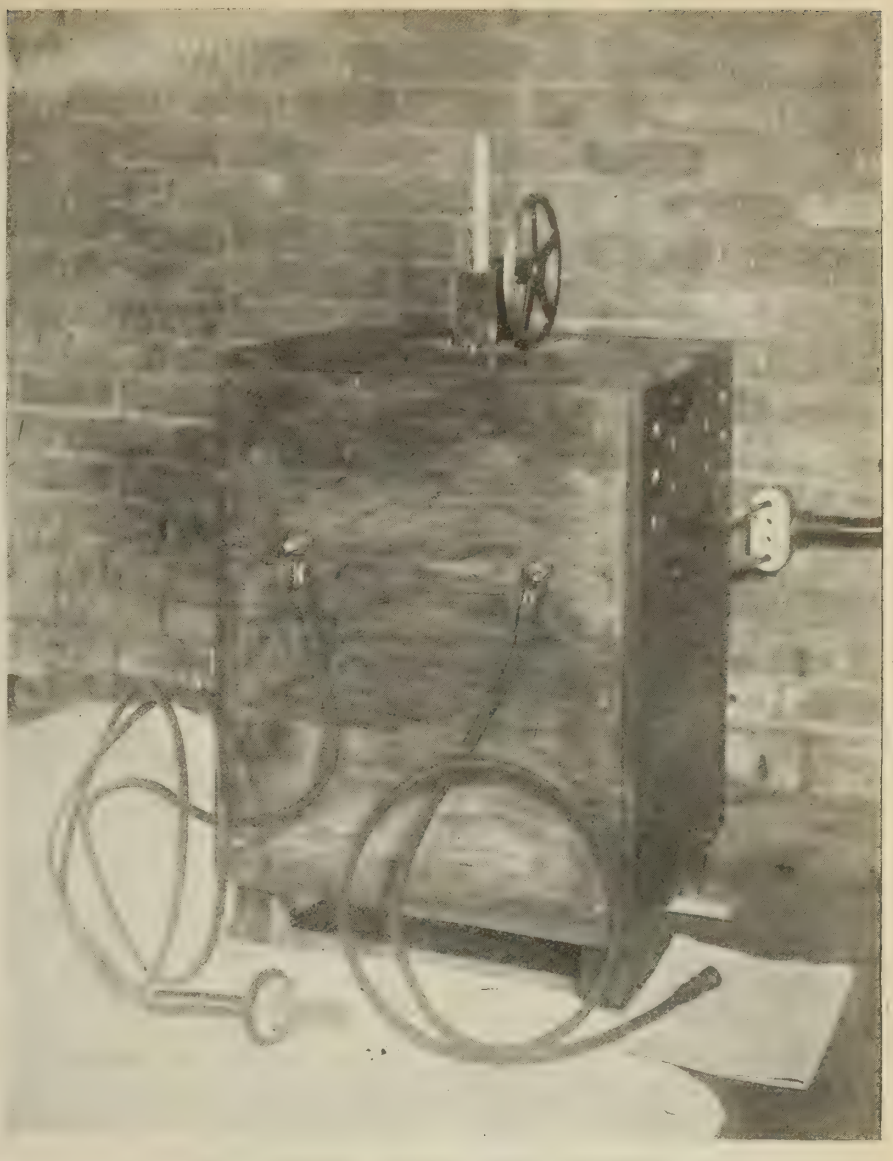

FIG. 1.—GENERAL VIEW OF THE APPARATUS.

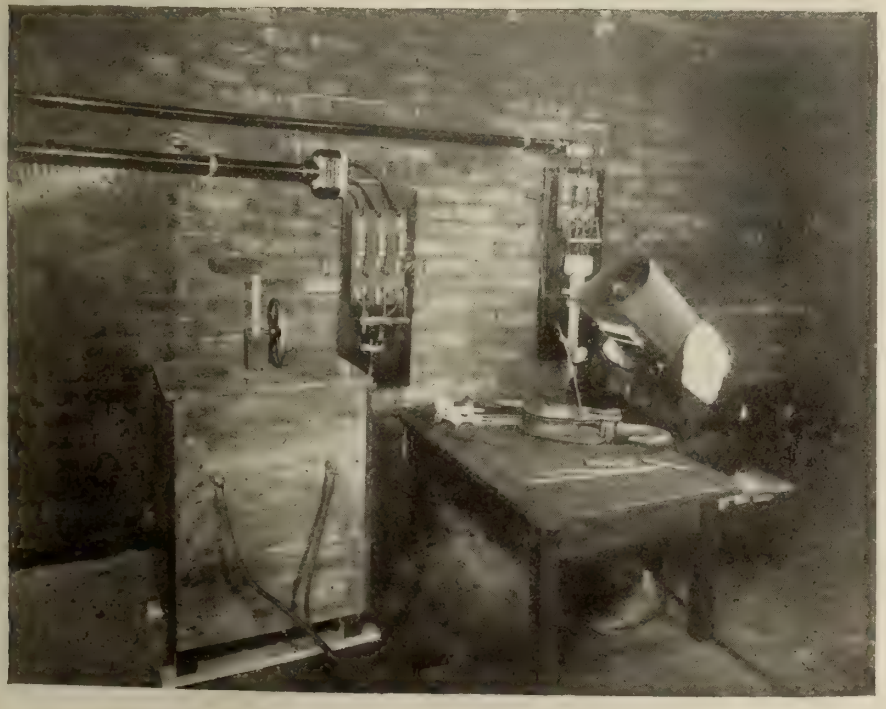

FIG. 2.—THE OPERATOR AT WORK.

One of the outstanding features of this welder is its arrangement for regulation. It is not necessary to in any way, change the connections in the regulation of the arc. A wheel connected with the secondary and extending through the top of the case, raises and lowers the secondary and provides for the regulation of the current necessary for different sizes of electrodes.

The inherent reactance of the "Z E U S" welder automatically stabilizes the arc for different arc lengths.

In addition to all its advantages, its cost is considerably lower than the cost of the types of the past.

Different methods are in use for keeping the supply of electricity steady in spite of the varying demands made on it. In some systems of distribution, instead of the two main conductors being one positive and the other negative, each is positive and negative alternately, the reversals taking place some hundreds of times a second. The current is then said to be alternating. When such reversals do not take place the currents are said to be direct.

Are Accidents Merely an Unnecessary Evil

Industrial Accidents Cost America 35,000 Human Lives and More Than $500,000,000 Annually—Is Such a Condition Necessary, or is a Large Percentage Due to Utter Carelessness?

By Master Mechanic

THE prevention of industrial accidents is a subject that at last is receiving the attention it so richly deserves. Although safety methods have been installed in various shops and factories throughout the country, still it is only in the last few years that any real systematic attempt has been made to reduce the accident bugbear.

There has been unfortunately a general fallacy existing that all work accidents were necessarily incident to industry, and that casualties were inevitable. How completely incorrect this assumption is, has been proved beyond the shadow of a doubt, by the splendid success in reducing accidents achieved by various safety engineers, and large industrial companies who have systematically attacked this accident problem.

Can We Prevent Accidents?

Not only has it been shown that accidents are preventable, but also that this prevention is not only profitable, but humane.

In 1916, there appeared an estimate of killed and wounded, which quoted the fact that the annual loss that year alone was greater than the combined losses of the Union and Confederate armies during the Civil War.

These figures cannot help but prompt the question: "Why so many accidents—were they all unavoidable?" which brings us up to a point where discussion is possible.

Accidents **can often** be avoided by exercising a little care and forethought.

An outstanding example is the Power Press. This machine was responsible, year after year, for the maiming of thousands of unfortunates, and the position of press operators was a hazardous one.

The same conditions exist in many "Safety First" campaign in motion.

At the present time in any up-to-date press room, it is the operator's own fault, and due to rank carelessness, should he lose a finger, for preventative guards of all descriptions have been installed for his benefit.

The same conditions exist in many other plants engaged in other lines of business, but for the purpose of this article, and to prove how carelessness is ofttimes the cause of accidents, let me mention a number of cases which have been cussed and discussed by the various parties concerned.

Some Examples

Let us start out with a very common form of carelessness, and the cause of many an accident—usually slight.

Did you ever see the tang of a file sticking out of the bench drawer(?). Of course you have, for unfortunately it's a common sight in the average machine shop. Usually a man opens the drawer hurriedly, slams in the file, and there you are. The handle sometimes stays on, sometimes not, then again often there was no handle on it at first. Someone comes along and without thought attempts to push it in the remainder of the distance, result—one more accident, usually slight, but in one case which came to the writer's attention, the outcome was blood-poisoning of very bad nature. Here is one case where a little care would make such an accident a thing of the past.

Then there is the chap up on the scaffold or platform, who will persist in leaving his hammer, chisel, wrench or some such article, just balancing on the edge. A slight vibration and down it comes, usually on somebody's head, sometimes luckily in such a way as to merely leave a bump, but often the victim receives a mark he never gets rid of. Here again, rank carelessness is the reason, and yet preach, preach, preach as you like, the same old condition continues to exist.

Oh, I Never Thought

Have you ever run across the type of workman who never bothers looking to see if there is any reason why he should not do the particular work he intended(?) The incident I have in mind was in connection with a boiler.

There was an inspector in the boiler, and on the job, watching him carefully from the outside, was the engineer. Naturally the engineer was very much interested to know what report the inspector would make, and on hearing a muffled remark from inside to the effect that his valve on top was leaking slightly he went up and without thinking(?) turned it the wrong way. Luckily he had presence of mind enough to realize what he had done and shut it off at once. Out came a badly scared and badly burned inspector. Here was a case where a locked valve would have been a real blessing. There is such an article on the market, which not only locks the valve, but has a tag which says, "Danger—man in boiler," yet here we have a case where no doubt the fact that such a thing existed was unknown. Was this accident unnecessary? We should say yes!

Don't Take the Short Cut

In a certain plant where safety first was believed in there was a sign as follows: "Never crawl through, over or under a belt." This sign was rather necessary, for there was one belt in particular, a 12 in. wide belt, which ran a pulp mill, and which ran over a space about three feet wide, a real nice short cut if you liked to take the chance. The belt was held together by a series of fasteners which protruded considerably on the side of the belt.

One chap in particular couldn't see the sense of this sign and kept on taking the short cut. He was warned, in fact threatened, but to no avail. He happened to be assistant superintendent or otherwise he would have been fired. Nobody seemed to think of blocking the path up with a real suitable guard. "You'll not bend enough some day," this fellow was told, and one day he didn't. When they picked him up he was dead, with his head practically torn in two.

And then, strange to state, a guard went up. What is the answer?

It's a strange fact that in spite of these different accidents, you will find the fellow who feels sure he's all right. He will usually tell you he has done this for the last five years and never got hurt, so why change his method now?

A case of this nature is well worth repeating.

This fellow was employed to attend to the oiling of all shafting in the plant under discussion. He was, to give him justice, an adept at handling a ladder, and so on safety feet for his ladder being suggested he pooh-poohed the idea. "What, me put those non-slips on the foot of my ladder, well I should say not."

However, time will tell, and on this particular day his ladder slipped. With great presence of mind he grabbed the shafting and hung on as best he could. Right below him was a paint mixer with its gears noisily letting him know they were very much there. It was not long before someone shut off the power and helped the victim of the accident down to terra firma once more.

His hands were badly lacerated and his nerve was badly shaken, and, what is more, he came down a convert to safety methods. His ladder received feet of the best non-slip variety, furthermore he exercised more care than ever before in the carrying out of his duty.

It may seem to the reader at this point that here we are croaking of all these accidents and mentioning only the gruesome cases, never touching on the lighter (?) side of trouble, but to illustrate that it is not the intention to show only the horrors of the situation let me quote a real funny incident that occurred some time ago in a machine shop in which the writer happened to be at the time.

Owing to bad judgment in the placing

of machines there were, strange to state, two planers in such a position that their tables ran in similar direction. It had never been considered possible that these tables could nearly meet if out at full extreme of stroke, but as luck would have it, one chap found this fact out, for in passing between these machines in an offhand manner he was pinned between the two tables. It looked mightily like a serious accident for a moment, but luckily the tables had reached the very maximum point of their strokes. Of course the yells of the victim could be heard for blocks, but he was more scared than hurt. All he really got was a steady squeeze, but he never takes short cuts any more, and these machines are now arranged in a different manner.

To show how similar cases have different results, let us quote another planer incident with an entirely different ending. The machines concerned in this case were a lathe and a planer, these being so arranged that often the space between the end of the lathe bed and planer table was very small. One day a workman was jammed in this space, and unfortunately so hard that he died inside an hour. Of course as per usual the stable was locked after the horse had left, for immediately after this accident the position of these machines was changed.

The Use of the Crowbar

A crowbar, like any other tool, has its own particular use, and this use is certainly not to pry around the flywheel of an engine under steam. Yet how often we see workmen using a bar under these conditions.

One incident that comes to the writer's mind is that of the attempt to start a huge hydraulic pump by means of a crowbar. "Did you close that throttle valve?" was the first question asked of the engineer before commencing operations. "Sure," came the answer back, and so the crowbar was inserted. But not for long, for suddenly wtihout warning, crowbar and men went off at a tangent to the flywheel at what a youngster would describe as some speed. Of course the reason is apparent, for although it was thought that the throttle valve was closed, still results proved it was only partially closed. Luckily nobody was hurt, merely badly shaken up, still, crowbars are not used for such purpose in this engine room at least.

Emergency Elevator

It is sometimes the most foolish idea that workmen will follow out, as for example the following incident.

It was desired to hoist a heavy casting, too large for the elevator, up to the fourth floor. The only solution was to knock out a small section of the outside wall and hoist up to this point. One fellow thought out the brilliant plan of using the shafting on the fourth floor as an elevator, so he wound the rope round the shaft and gave orders to start the motor. He omitted, however, to notice a loose loop of rope which caught his foot when the motor started, with the result that it carried him up to the shaft, and before they could stop the motor he was dead.

But these stories of lack of thought could go on indefinitely, for case after case has no doubt cropped up in readers' minds while they have been perusing this article, so, with a closing example, the writer will close.

This incident happened in quite a large manufacturing concern where there were men who were paid high salaries to know better, and they did no doubt realize that the scheme adopted was a risky one—but to go on with the story.

They were moving a large motor down an incline of about 25 degrees. This motor was of such width that all the weight would rest on two boards of the portion on which the same had to slide, so for safety's sake it was deemed wise to place crosswise on this boarded incline two large doors on which to slide the motor, this of course distributing the weight evenly.

All went fine, and the motor was coming down in splendid shape. Only 4 feet more was necessary to bring it to the level, and it seemed a shame and a waste of good time to move and place a door under the motor for such a small distance. It was suggested that they take a chance (I use the term advisedly) and skid her down without the aid of the door.

They tried to do so, and as soon as she came off the door one of the feet plunked through the board, the motor swayed with the impact and toppled over sideways on to the cement below and smashed some parts of it, which took over two weeks to replace.

Of course there were some men lost their jobs over this incident, but that didn't help the motor any. Here we have a plain case of foolishly taking a chance in order to save a few moments' time.

It is this fact of rush, rush, rush, that causes so many accidents. As readers have no doubt read elsewhere, the A B C of safety first is, "Always be careful," so when tempted to rush matters, think of these three words and be careful rather than sorry.

The final question is this: "Are accidents absolutely necessary, or are a great percentage due to carelessness and lack of thought as described in the previous examples?" at which point the writer leaves readers to their own thoughts on the subject.

GUNPOWDER SAVES

A somewhat novel idea is in successful operation in the machine shops of the D. & H. R. R. Co., at Watervliet, N.Y. They are using ordinary black sporting powder to save the time of mechanics as described below:

Used for blowing nuts and bolts (sweated on) of which there are many in the construction of locomotives and other railroad equipment.

Breaking up iron and steel to be scrapped.

Forcing off a piston (locomotive) when rust or corrosion binds it.

Breaking metal which has become cold in a furnace (this has been done at this plant without breaking a firebrick).

Methods of Use

The charge of powder in all cases is loaded in steel guns of various sizes and held by a steel plunger, which is forced out when the charge is set off. No wad is used. The plunger is milled to a size to fit (easily) the bore of the gun.

They have these guns in sizes, from end to end, of 5 to 12 inches, with other dimensions in proportion; also dimensions for plunger to sink. Some of the gunbarrels are milled in the shape of an octagonal prism instead of being cylindrical; the bore in all cases is round.

The gun, after loading, is jacked up with the mouth within about one inch of the object to be struck by the plunger, and fired. They use approximately 1 oz. of powder per nut or bolt (sizes in common use on locomotive construction) which is to be broken off or loosened. The load, of course, is varied with the work to be done. I mention the amount for bolts and nuts because this is the commonest practice with the gun.

By the use of these guns, they claim, much time and labor has been saved; also, a sharp, quick blow can be directed at an object which is barely reachable otherwise.

BOILER EXPLODES AT JOYCEVILLE

Continued from page 157

Joyceville boiler was of the kind usually reckoned by the farmer class to be without possibilities of danger. The accident clearly shows what a small boiler can do if it explodes.

The Remedy

The remedy is so obvious that it hardly needs suggesting. It is the plain duty of the Government to put its inspection departments on a basis that will enable them to keep track of every steam boiler in the province. Where there is danger to life, petty economies should not be considered. Five or six inspectors for a province the size of Ontario are hopelessly inadequate, and it is to be earnestly hoped that steps will be taken before any more fatalities occur.

Accidents in the iron and steel industry have decreased by more than two-thirds during the past 10 years as a result of the movement to enforce safety regulations, according to a report recently made by the Bureau of Labor Statistics. In 1907, the report shows, 245 men were killed or injured out of every 1,000 employed, while in 1917 the accident rate was reduced to 81 per 1,000. A further reduction would have been recorded in 1917 but for the dislocation of industrial processes to meet war needs, the report adds. The majority of accidents are declared to have resulted from defective machinery and the employment of inexperienced men.

WHAT OUR READERS THINK AND DO

RADIAL BORING FIXTURE

By J. J. McIntyre

MACHINING operations out of the ordinary are not plentiful, but the method described here for boring "round a corner" is away from the "beaten path."

The Lamson Conveyor Co., of Lowell, Mass., makes conveyor systems for carrying mail through underground tubes at Washington, D.C.

These tubes are 8 in. in diameter in the bore. All right angle turns are made on an 8-foot radius. It is the boring of these sections that the turn makes necessary that the attached sketches explain.

Fig. 1 gives the requirements that have to be met. Each section, of which there are four, comprises an arc of a little over 3 feet in length. Each section must be bored smooth on an 8-foot radius so that the mail carrier will not get stuck when it shoots around the corner.

After the four sections are bored they are drilled for bolt holes on the flanges and are later secured by bolts when assembled.

The ingenious set up represented by sketch Fig. 2 and attached photograph will help to make the method understandable.

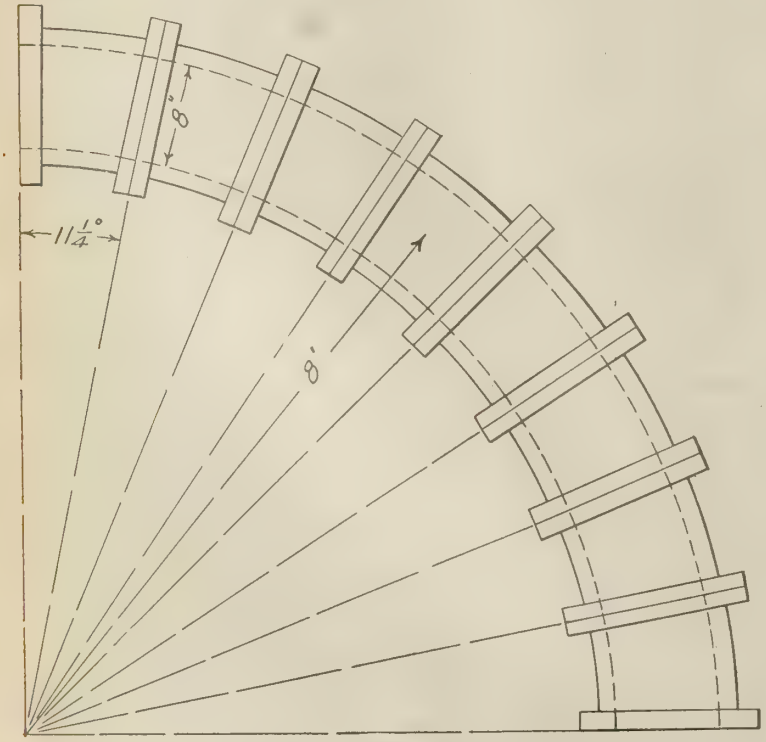
The method involved is that of machining Stephenson locomotive links applied to a horizontal boring mill.

The work-holding cradle is made to pass by the revolving cutter head on an 8 ft. radius by the aid of the longitudinal feed of work table which is free to move at right angles to spindle of machine—the crossfeed nut is removed to permit this.

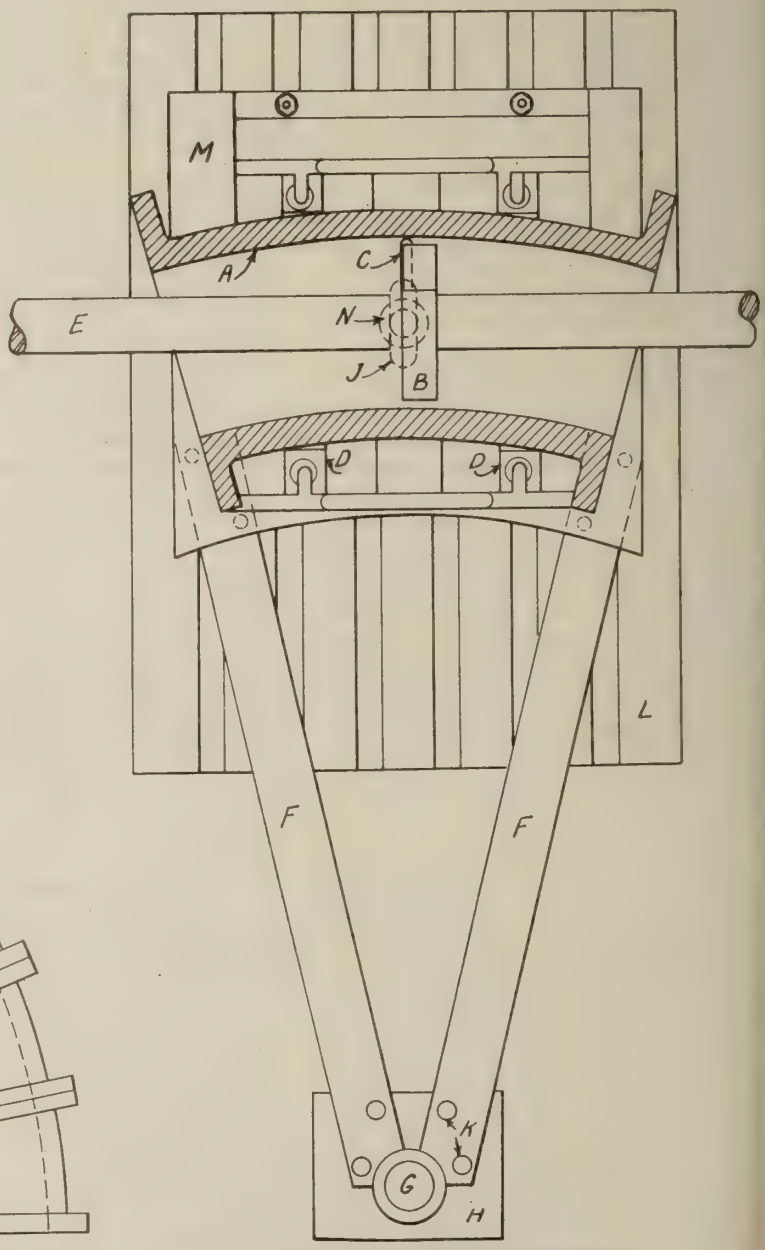
The two stops D hold the work A in the cradle. The cutter holder can be pinned or held by screws on shaft E.

Boring around a corner becomes a reality when the procedure described here is followed out.

When this operation was first proposed it was declared to be impossible of execution; however, the design proved workable and the above concern has accomplished the machining of a great variety of radii and different sized bores.



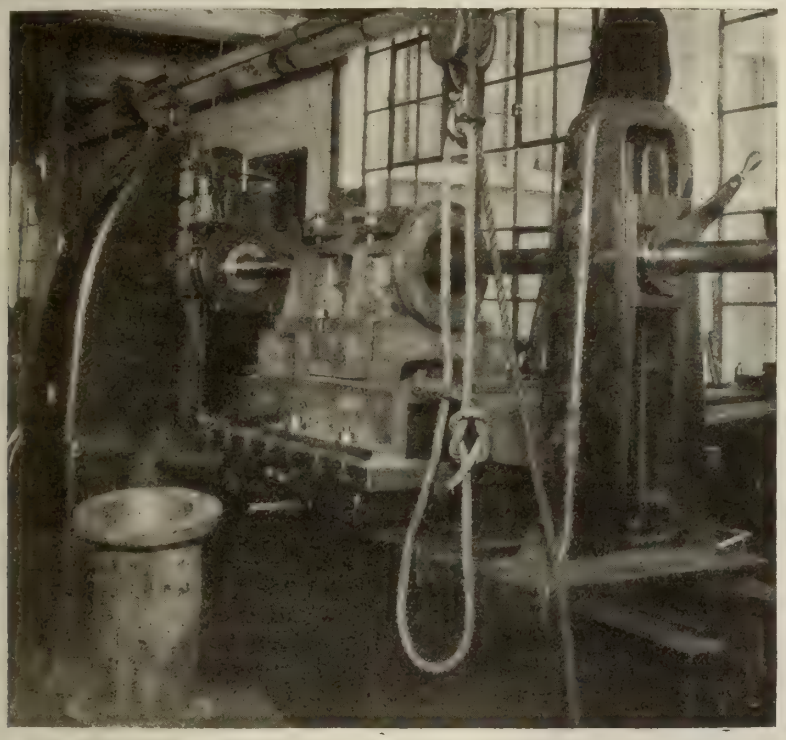
A VIEW OF EIGHT SECTIONS OF PIPE.



SECTIONAL VIEW OF ARRANGEMENT.

There is of course a certain relation between the size of hole and diameter of spindle that holds cutter holder. The smaller the diameter of spindle the shorter the radius that can be machined.

The centre of the 8 ft. radius is a bushing G that fits over a stud set in a concrete pedestal and securely held by melted sulphur. The plate H which holds bushing G has also attached to it the two arms F, which serve to move the



GENERAL VIEW OF THE FIXTURE.

work-holding cradle in unison with the longitudinal motion of table. The elongated slot J, in which works the shoulder stud N, serves to hold the cradle to the table, also by the aid of two bolts in back, the stud and two bolts are just loose enough to permit the cradle to slide without shaking.

The cutter C on spindle E revolves in the same plane—the work passing it on an 8 ft. radius. The proper distance of cutter from spindle head gives a perfectly round hole—this must be found by experiment—if the cutter is not set the correct distance from head an elongated hole will be bored.

DOUBLE SPINDLE ATTACHMENT FOR LATHE

By G. BARRET

The fixture, as illustrated, was made to fit a standard lathe, and equipped to turn two drums at the same time.

These drums are used on a textile spinning frame for variation of spindle speed.

This fixture is attached to lathe in the manner shown, and is worked by the gear A (see Fig. 1), which is made to screw on to the lathe spindle. This gear meshes with pinions B and C. These pinions are keyed to shafts D, which receive their bearings in a special bracket, E (shown at Fig. 2).

These shafts are made of cast iron and the driving plate is cast solid and machined all over, then bored to suit lathe centres.

The casting F on the tail stock is made pretty heavy and bored to suit tailstock spindle; also for two steel centre holders, G and H, which are shrunk into casting after being bored.

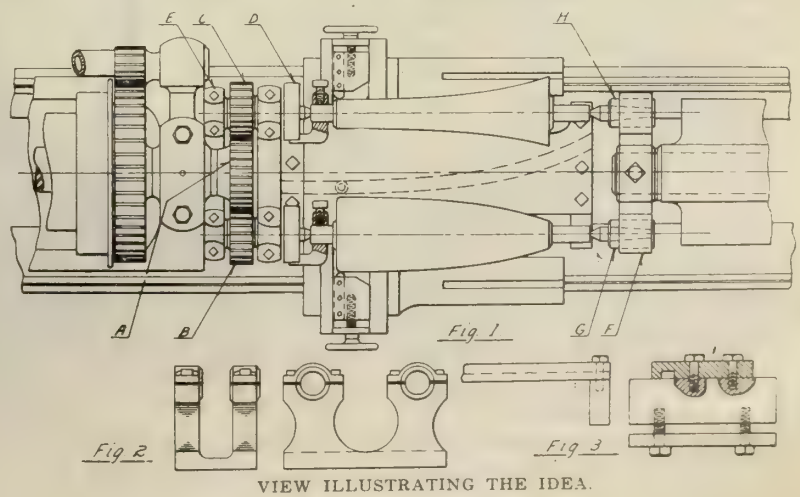
The cam plate is made to straddle the cross slide, so that the roller is free from castings while in operation. The method of fastening this plate to lathe is shown in section at Fig. 3.

The regular cross slide is removed and replaced by a special slide made to suit width of lathe and gears used for driving purposes.

As the adjustment for cuts is but small, the tool blocks are made to move by a small screw and handwheel, shown in drawing.

The front block is made high enough to allow the cutting tool to operate above centre, as the front drum is caused to revolve the reverse way by the gear and pinion, A and B.

This attachment not only produces two articles at once, but they are bound to conform one to the other.



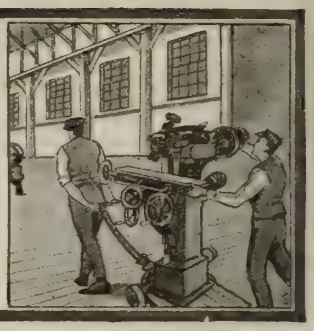
VIEW ILLUSTRATING THE IDEA.

Until lately a handsaw was one thing and a circular saw was another. But now an enterprising manufacturer has brought out a portable tool in the shape of a hand circular saw with electric drive, that should make sawing wood a pleasure. A ¼ h.p. universal motor is mounted directly on the tool, which has a handle like a regular handsaw and weighs only 12 lb. Two 3-in. saws are supplied, a rip and a crosscut, an eccentric mounting allowing adjustment for depth. The base, of aluminum, is grooved to slide on a track when a guide is necessary, such a track being part of the equipment. For ripping, the gauge slides along with the work. The saw blade is well guarded, so the tool is particularly adapted to manual-training school use. It operates from any lamp socket, direct or alternating current.

It is safe to predict that destructive forest fires will soon go out of fashion as a result of the many preventive measures being taken. Quite the latest is the forest balloon service. Experiments at an army balloon school have shown that the innovation is entirely practicable, and most efficient when in the hands of trained observers who can spot a blue wisp of smoke miles away. The observer's telephone will be an essential part of the system that will spread the fire alarm through the great forests.

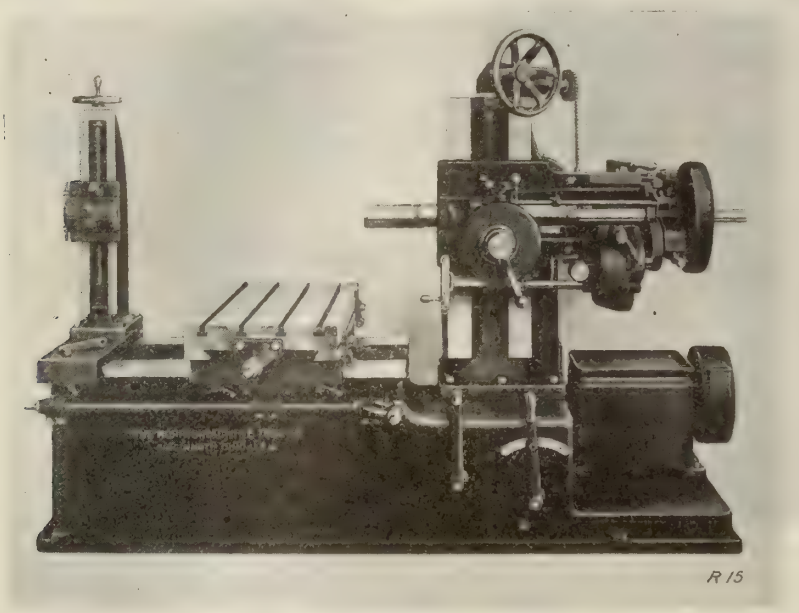
By hinging the ordinary carpenters' steel square, and providing a third strip, calibrated in inches and degrees, to connect the two arms, a folding square has been obtained that may be put to many uses. It may be clamped to lay off anything from a straight line to a right angle; it will divide any angle as desired, or it may even be extended, clamped and used as a yardstick. Besides making several instruments superfluous, the tool will fold into the carpenter's tool box, unlike the cumbersome rigid square.

DEVELOPMENTS IN SHOP EQUIPMENT



MORRIS HORIZONTAL DRILLING AND BORING MACHINE

THE horizontal drilling and boring machine shown in the illustration has just been placed on the market by the Morris Machine and Tool Co., Cincinnati, Ohio, in answer to a demand for a machine for drilling, boring, facing and tapping operations. The bed is of one-piece box section, ribbed internally, and runs down to the floor. The column is also a box section and is bolted to the base. The bed moves on ways arranged with taper gibs, adjustable for wear, and is counterbalanced, the handwheel at the top of the column serving to raise or lower the head. A steel scale graduated in sixteenths of an inch is set into the column, and this in connection with the micrometer column on the head elevating screw enables readings in thousandths to be obtained for the full travel of the head.



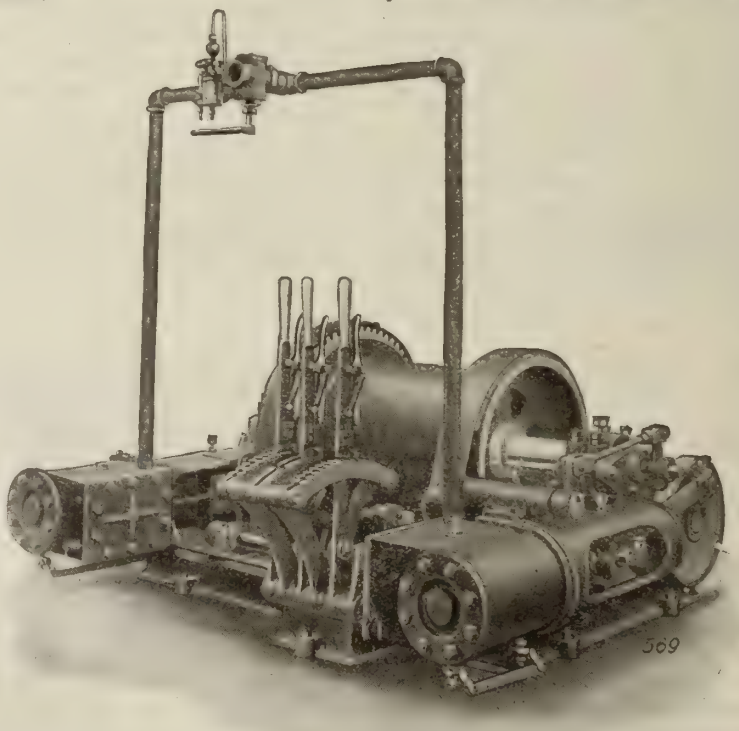
GENERAL VIEW OF THE MACHINE.

The spindle is of forged high-carbon steel ground to size, the thrust being carried on ball bearings. The sleeve is graduated and provided with a direct-reading depth gauge. The spindle drive gears are helical, this construction giving smoothness of action and the elimination of chatter. The back gears are of 3½ per cent. nickel steel, heat-treated and hardened, and are fully enclosed and mounted as a unit on the back of the head. The speed box is mounted on the bed with the gears fully enclosed and running in light grease. Six speeds are provided, controlled by two vertical levers on the front of the bed below the column. The lever at the left controls the double friction clutch and pulley shaft, and the other lever the three sliding gears. The feed box is also a unit mounted on the head, the gears being enclosed and running in oil. Six speeds are provided that can be automatically tripped at any depth within the traverse of the spindle.

The bearings throughout are of bronze arranged with oil chambers, the oil being drawn into the bearings by felt wipers. The machine shown is for belt drive, but motor drive can be furnished if desired. In this case a three-to-one variable-speed motor is connected to the lower shaft by one pair of gears or a constant-speed motor used in connection with the speed box.

A NEW LINE OF MEDIUM AND SMALL STEAM HOISTS

REALIZING the demand for medium and small-sized high grade hoists for mining and industrial purposes, the Canadian Ingersoll-Rand Co., Ltd., has placed on the market a line of such hoisting engines, embodying many new features of design which will commend themselves to those who are familiar with the usual construction of machines of this class. These improvements have been adopted as a result of their long experience in the manufacture of mining

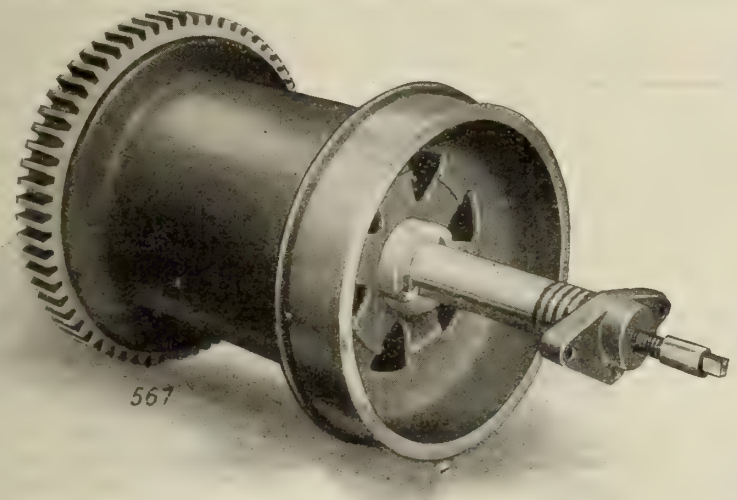


GENERAL VIEW OF 7 x 10 INCH. SIZE NEW "CIRCO" STEAM HOIST.

machinery and contact with users in all parts of the Dominion.

During the war this firm, which was one of the largest producers of shells and shell machine equipment in Canada, also built several hundred ship winches for the United States Emergency Fleet Corporation, the Federal Construction Co., the Foundation Co., etc. In starting to manufacture this new line of hoists they decided to design jigs and fixtures, and produce the engines in quantities, on the interchangeable part system which had proved indispensable in the rapid production of ship winches, and which has been one of the most important factors in the development of the modern automobile and machine tool industries.

While the company is ready at all times to make these hoists in larger sizes on special order, they are at present concentrating on the production of five sizes, ranging from 6x8 to 10x12 inches, with lifting capacities which are conservatively rated at from 4,000 to 10,000 pounds.



DRUM, DRUMSHAFT AND FRICTION OPERATING DEVICE OF NEW "CIRCO" STEAM HOIST

Some of the interesting points in the construction of the new Circo hoists are as follows:

The cylinders are cast separately from the side frames and are interchangeable, thus permitting one spare cylinder to be used on either the right or left hand side of the hoist, and doing away with the scrapping of the side frame of the hoist should one of the cylinders become accidentally damaged in some way.

The exhaust may be connected to either the top or bottom of the valve chest when the hoist is operated on steam as may be most convenient, the opening not in use being plugged. In case it should be desirable to operate the hoist by compressed air for any reason, this extra opening will be found valuable as it will enable the air to exhaust more freely than is possible with the old style valve chest. The cylinders are bolted to the side frames by strong turned studs and faced nuts, and the walls are amply heavy to permit operation at maximum pressure after reboring.

The interchangability of the cylinders is typical of the construction of the entire machine, every part being made to close limits, of the best materials and thoroughly inspected throughout the various steps of manufacture. As the hoists are so easily dismantled they should prove of special value in the case of isolated mines where the machinery has to be transported long distances by horses or mules.

The valves are of the plain slide type and are provided with an adjusting device which automatically compensates for wear without changing the original alignment of the valve rods. The valve rods are guided by carefully fitted babbitted cast iron guides attached to the side frames.

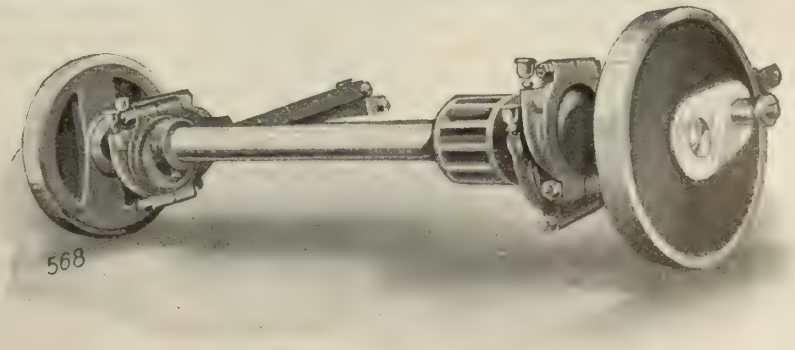
Locomotive type eccentrics are used, which are characterized by deep, flat rods bolted to the straps by turned bolts in holes which are reamed after the valves have been set, preserving the accuracy of the original setting. The eccentric straps are provided with large bearing surfaces and are adjustable for wear.

Connecting rods are of steel of the solid end type, having bronze boxes in both the crank and cross head ends, provided with wedges and screws for taking up wear. The screws are made adjustable in opposite directions, so as to insure approximately the same length in each rod. The crank pins and shaft are made of the best grade of open hearth hammered steel fitted to the cranks (which are of the counterbalanced disc type and finished all over) by hydraulic pressure. To insure accuracy the discs are turned and the crankpin holes bored after the disc has been pressed on the shaft.

The drum shaft bearings are bolted to the side frames instead of being cast integral as has been the usual practice for many years. A high grade of babbitt is used in these bearings and they are adjustable for wear. The drum is made of close-grained cast iron, turned, bored, and tested for a good running fit on the drum shaft. The bearings being bolted to the side frames ensures accurate alignment of the shafts and easy running gears. A heavy brake ring is cast on one end of the drum, and on the other a friction of the heavy V type which has proved its efficiency for this class of service. The brakes are so proportioned as to have a holding capacity considerably in excess of the maximum lifting capacity of the hoist, which is of value in case of emergencies, or should the hoist be overloaded. The drum driving gear and the pinions are made from semi-steel, a material which has been found well adapted for this purpose. The pinion is keyed to the crank shaft so as to permit its ready removal when necessary.

When reversing engines are ordered the hoists are fitted with a Stephenson type reverse gear, operated by a hand lever with quadrant and locking latch, which for ease in operation, is placed with the clutch and brake levers in a stand near one of the cylinders, thus grouping all of the control levers near the throttle, and within convenient reach of the operator.

This firm also builds two styles of hoist of smaller capacity than their new Circo hoists, which are known as the "Special" and the "Little Tugger" types. The former is of the diagonal reciprocating type, with trunk pistons, and the latter of the square piston or Dake type, both of which may be adapted to operate on either compressed air or steam. Being of rugged construction and requiring no special foundation they are readily moved from place to place, and have a wide range of usefulness where the requirements are within range of their capacity, which is 1,400 pounds in the "Special," and 1,000 pounds in the "Little Tugger."



CRANKS, CRANKSHAFT, ECCENTRICS AND PINION OF NEW "CIRCO" STEAM HOISTS.

A Dangerous Thing To Do

MAKERS of boots and shoes are seeing to it that advance notices are being well circulated to the effect that prices of boots and shoes are going to "increase enormously."

The same is said of clothing. It is not at all necessary to stop at these two lines, but they are taken because reference to them has been made very recently in all sections of the press.

Just how long the public temper will stand for this sort of business is problematical. It is a safe guess, however, that every price boost has its effect on the public mind. How long can this sort of business continue without the strain becoming greater than the temper to stand it?

Manufacturers of all sorts, no matter if they are turning out the finished product, or semi-finished, or raw material, know as well as any other class of people that labor troubles are greater now than they have ever been. They know, unless they are too blind to admit it, that the failure of a strike to win does not mean that labor unrest has been cured. It means that it has been aggravated, and unless conditions change it will break out anew.

Ask many of the men who are strikers, or who have been, what is their complaint. Make allowance for the agitators and all the rest of that ilk, but see to it that you listen seriously and honestly to the man who would much rather work than strike.

What is his complaint?

Simply this: His expenses are increasing to such an extent that his wages cannot keep up. He is going behind. He has not the power to force all those with whom he does business to see that his dollar buys more than 52 cents' worth. All he can do is reach out and try and increase his earning power.

If boots and shoes "increase enormously," and if clothing is "much higher" the wages of men who have to buy these things will either have to "increase enormously" or go "much higher."

Now this is a very real and a very dangerous situation. Right now, when this whole continent needs production, needs a co-operative feeling between shop and office, needs fewer strikes and fewer lockouts—right now, we claim, it is nothing short of crime to upset and disturb the public mind with notices of further increases in the prices of those things that people must buy if they are going to live decently.

The man who will bluntly stand, in the face of all the labor unrest, and tell that his company's profits were 70 per cent., and that the business was not run for the glory of God, but for the shareholders, is lacking in his sense of appreciation of what citizenship really means.

The men who, as individuals or corporations, are responsible for sending out intimations of large increases in the necessities of life, are likewise barren of any indication that they realize the seriousness of their movement.

If men are going to continue to make the grabbing off of dollars the greatest job in the world, then we are going to have a tremendous heap of trouble, and it is very doubtful if it will be possible to shove in the peg at the stopping point we may think desirable.

To those in authority to-day, both in Canada and United States, we would say: "Gentleman, do not wait until the crowds parade the streets with bricks, or until they start to shoot; don't imagine these things are impossible. They are not. They are dangerously probable."

The man who is seeking, even after what we have passed through, to mulct the public, and to make it harder for men to live decently, is a menace to the peace of the country. The jail is the only place for him, and the sooner he is securely locked there the sooner can we go ahead and attend to our right and legitimate business.

Tinkerin' John

HE was just a sort of a handy man as he canted around the shop, and everything got done the same with a kind of a skip and a hop. He did odd jobs and just filled in whenever a chap was off, with the gout or rheumatiz or such, or nursin' a graveyard cough.

But they'd never give him a steady job, this tinkerin' chap named John, for fear that somethin' he turn or do would have a chance to be wrong. So he puttered around at this and that, and he worked from bell to bell, but Tinkerin' John could never do a particular job real well.

Oh, Ive seen a heap of tinkerin' Johns; you meet them East and West, and they couldn't, to save their bloomin' hides, name the job they could do the best.

They can tinker at this and tinker at that, and they're handy to have around, and they always stay on the ladder quite near where it hits the ground. And when there's a chance to go higher a bit, where pay is both thick and long, they never turn to give a chance to this here tinkerin' John.

Oh, I've seen a heap of tinkerin' Johns; you meet them up brown, and do it better than any chap what's campin' in the town. It's great to see the hand of skill linked up with a mind that's keen; that can take any job that comes along, the fat as well as the lean—and can do the thing bang up each time with never a flaw to spoil—it's chaps like them that help to bring real honor to honest toil.

But tinkerin' John, he's always here, just fiddlin' his years away; a sort of a handy chap to have and never one hard to pay.

There's a bit of a sermon here for you—don't dodge nor pass it along—if you want to get to the top of the heap don't be just a tinkerin' John.—ARK.

The Case from the Draftsman's Point of View

By One of Them

IT is quite refreshing in these modern days of camouflage to read an article such as written by one who signs himself "Engineer," on page 79 of your July 24th issue of CANADIAN MACHINERY.

Evidently this engineer is also a draughtsman, otherwise he could not discuss so freely and intelligently the ins and outs of the situation. There is a saying that, United we stand, divided we fall; so if I may be allowed a short space I will try to confirm and establish some of the points brought out by the original article, at the same time slipping in a few ideas of my own.

First and foremost, the writer remarks, "Yea, verily," to the suggestion of making a dividing line when speaking of draughtsmen, designers, detailers, and tracers. Why should the chap who has industriously stuck to his guns, studied evenings at home, or at school, and read up up-to-date technical literature, get a paltry two to five dollars more a week than the other fellow, who merely puts in his seven or eight hours a day, as the case may be? Do you blame the chap who has the ambition and initiative grouching at the unfair value placed on his ability?

Such a condition will remain in vogue just so long as employers continue to view their drafting staff as an organization, which, unfortunately, has to be put up with.

Some readers might not be inclined to agree with this remark, so, in order to prove at least one case in point, the following tale is told.

In a certain munition plant (never mind the name or locality), machinists were making on an average of 70c to 80c an hour; toolmakers were drawing as high as $1.00 to $1.25 an hour; hunkies, or to be more kind, general handy men, who had learned one particular operation on shell work, were drawing as high as $100.00 for the week's work of 10 hours in the day. Draughtsmen, all kinds, designers, detailers, etc., etc., were drawing from $90 to $125 per month, not per week. Why?

To heap coals of fire on their humble heads, as it were, this firm paid bonuses to all help mentioned, with the exception of the drafting staff. This, naturally, peeved the pencil pushers, who timidly requested enlightenment as to why such a state of affairs existed. "You fellows are 'non-productive'," was the laconic answer.

Do you blame the average draughtsman for having very thin hair on top and none in front if he must listen to such a tale. No wonder he pulls his hair out. Who designed the tools for this plant spoken of (?) Could the toolmakers, all respect given them, have designed, as well as assembled the dies, etc., required? Without the dies and tools could the handymen have turned out the shells? Yet the poor draughtsman was non-productive.

And now we will talk of the average apprentice, who is on his last stage of apprenticeship and about to become a full-fledged designer (?) all in his four years' experience.

Personally, when the writer had completed his four years he was only beginning to sit up and take notice, yet he had never slouched on the job, but tried to stick to his guns, studied evenings, read all possible literature, especially on tool and jig design, which was the particular field he was interested in. This brings us up to the point where we ask the question: "Is four years sufficient to make a draughtsman?" The writer's answer would be: "In four years you can make a draughtsman, but not a first-class designer, especially with the average system now in vogue."

The writer agrees strongly with "Engineer" that actual shop experience is absolutely essential to an apprentice if he desires to become an intelligent designer. The machine shop, tool room, patttern shop, and foundry, should all form a part of his training. He should now, at least, be a real designer if he has paid attention to all these branches. Of course, the old point crops up once more, that after he has mastered all these little trifles (?) he receives the usual average salary meted out to the slaves of the drawing board.

Readers might well say, "Why should an apprentice require such wide training?" To answer such a supposed question let us first suppose we are in the machine shop watching a planer hand at work on a large bed of a machine, one surface of which is being planed, not all the way through, but which must be stopped at a certain point. To those acquainted with the machine-tool trade it is not necessary to state that certain allowances must be made for tool clearance purposes, where the stroke of planer trips and reverses the direction of the table.

We, in imagination, see this planer hand stop his machine to chip out a clearance space for his tool, at the same time cussing draughtsmen in general for their lack of brains.

We now, still in imagination, go to the drafting room, where the chief has heard of the trouble spoken of. "Say, why didn't you leave clearance for the tool on piece so-and-so?" he asks the draughtsman responsible for the blunder. "I did," comes back the answer, "I allowed over ½ in. long and 1-16 in. deep. Wasn't it enough?"

If this chap, who we have been imagining about, had spent even one day on a planer, he would not have made such an apparent blunder. Of course, all are not like this, but the extreme example is mentioned to bring out the point that actual working conditions must be known before a designer can design to the highest point of efficiency.

Then again, by a good understanding of pattern making many a dollar can be saved in the drafting room. The same holds good for the foundry in regards to castings, which, I believe, will convince the doubtful reader, if any, that shop experience is essential in the making of a real honest-to-goodness machine-tool designer.

All these knocks and grumblings may sound as if the writer has a personal grouch at the business. To those who have read this far let it be said that the writer wishes he could work up a real sized grouch at the trade, sufficient to disgust him enough to leave it, but no—the fascination of the game is too much for him in spite of its disadvantages. Sometimes it seems as if the employers have secretly found this weakness out in the average designer, and play on it for all it is worth.

There is many a designer to-day who realizes only too well he is underpaid, and yet loves his job of creating things in general too well to leave it for something more lucrative.

Is there any remedy for this situation, or is it something which simply must exist?

To the writer's opinion there is a remedy, but one not likely to occur. The remedy that has been employed with so much success by the branches of the engineering trades outside of the drawing office, can be applied to those in it. That is, if they can get together and compose their own differences and adopt a real standard of efficiency with a minimum reward.

Coal for Bridgeburg.—Bridgeburg received its first coal for the season this week. Consumers are now being supplied, but coincident with this comes a warning from D. A. Coates, of the Provincial Natural Gas Co., that gas will be increased forty to fifty cents per thousand in September next. He also warns consumers to use gas for cooking and water heating only, as if they use it for house heating there will be a gas famine.

Worth-While Information From Many Points

In Chicago there is a bureau devoted to finding employment for men 45 years and over. It is estimated that over 20,000 men have thus found employment. In practically every case the concerns who hired the men came back for more, which proves you are not by any means a dead one at 45 and over.

* * *

Mixing dry colors in ready mixed paint with the ordinary paddle to get the desired shade is a decidedly tedious job and unless thoroughly mixed will be streaked and spotted when applied with a brush. A much quicker method of accomplishing the mixing is to use an egg beater, which also eliminates the skin and other foreign matter from the liquid.

* * *

The British Government has decided to offer a prize of $10,000 for a process of making a mixture of dehydrated coal tar with mineral petroleum oils suitable for Admiralty use as fuel oil. This will be awarded to the first competitor submitting a successful process which must be capable of ready and economical application without undue absorption of material and labor.

* * *

If two parts of copper and one of tin are mixed, it makes a white alloy which has a brilliant lustre, and will take a high polish. This alloy is known as speculum metal, the technical name for telescope mirrors or reflectors. The addition of 1 or 2 per cent. metallic arsenic makes the metal more compact and gives it a greater lustre and hardness, but renders it liable to be tarnished. It is nearly as hard as steel and as brittle as sealing wax.

* * *

Tracings may be very readily cleaned and pencil marks removed by the use of benzine, applied with a cotton swab. It may be rubbed freely over the surface without fear of injury to the lines drawn in ink, or even water colors, but pencil marks and dirt will quickly disappear. The benzine evaporates almost immediately, leaving the tracing unharmed. The surface, however, will be somewhat softened, and should be rubbed down with a little powdered talc or chalk before drawing more ink lines.

* * *

The metal layers of an engine that come in contact with one another rub off small articles of matter that combine with the lubricant used and form a dirty and sticky mess. The olein contained in the lubricant will in course of time form an acid, known as oleic acid, which has a deleterious effect on the metal parts that it touches, causing progressive corrosion. But luckily, it is only when its oleic-acid content exceeds one-quarter of one per cent. that an oil becomes unfit for lubricating purposes.

Celluloid articles can rarely be restored to their original whiteness if they have been thoroughly discolored throughout, but if merely superficially discolored, wipe them with a woollen rag wet with absolute alcohol and ether mixed in equal proportions. This dissolves and removes a minute layer of the surface being cleansed and lays bare a new surface. To restore the polish rub briskly with a woollen cloth and finish with silk or chamois. A bit of jeweler's rouge will greatly facilitate matters.

* * *

Electric current is available to most people, but it is not always apparent whether it is direct or alternating, 110 or 220 volts. A new pocket instrument, 4 inches long, 2 inches high, and 1½ inches wide, has a dial at each end in which the letters "A. C." or "D. C." appear, as the case may be, when the flexible cords are connected to the circuit. The voltage is indicated in the same manner. Provision is made for connecting to any kind of terminal, a plug being provided into which the posts on the wire-ends fit, for lamp-socket testing.

* * *

Lead poisoning is being investigated these days, because of its widespread existence in various industries. The Working Conditions Service, Department of Labor, has prepared, as a guide to industrial physicians, a schedule for the physical examination of lead workers, in which provision has been made for covering not only the typical manifestations of lead poisoning but also for bringing out the previous history of the worker, to determine whether hazards in other industries may have had an adverse effect upon the health. This schedule has been forwarded to districts in which lead poisoning in the pottery industry has appeared.

* * *

Regulations have now been laid before the British Columbia Legislature in which there is to be the provision that every winding rope shall be given a bath in hot oil before being installed; that every winding rope shall be recapped at intervals of not more than six months; and that no winding rope which has been in use for more than two years, or which has been spliced, shall be used for raising or lowering persons. No cable is to be used for more than two years for raising or lowering persons. In this country the Royal Commission on Mines in 1909 recommended that winding ropes should be allowed to be used for three years and six months. To prevent crystallization of chains it will be provided in the new B. C. regulations that all cage chains in general use shall be annealed once at least in every six months, and detaching hooks shall be cleansed and refitted once in every three months.

* * *

Word comes from the north-east coast of England of a vessel that has been designed to meet the need of an unsinkable ship. To accomplish this end the bridge of the ship is made watertight, and is made large enough to accommodate all the people and valuables on board. It is not made integral with the ship, but is attached thereto with easily-detached fastenings, and in the event of the hull being mined or torpedoed, the bridge will have enough buoyancy to float and sustain the weight of the immersed hull. The crew and passengers can remain in the bridge until taken off or towed into safety. If the hull through very bad weather becomes a danger to the bridge it can be released and allowed to sink, leaving the bridge afloat.

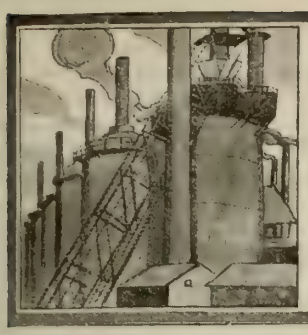
* * *

Stamping, drawing, and general press work on cupro-nickel can be accomplished as easily as with brass, according to the "Metal Industry." The metal can be more drastically treated, and stands greater reduction than brass, although more power is required than for working most alloys. Annealing cupro-nickel articles between operations is not advisable, chiefly on account of the great tendency toward fire-cracking and the production of excessive scale, which is very difficult to remove, and which, unless entirely eliminated, will ruin punches and dies.

* * *

Zinc water pipes which come in contact with mortar containing gypsum become in a relatively short time corroded and eaten through. Where the surface is wetted and quickly dried a protective coating of zinc oxide is formed, but where the contact with running rainwater is prolonged, such as in the case of roofing plates and gutters, energetic action must be reckoned with. According to "Building News," the most active agent of destruction is sulphate of lime. Zinc is energetically attacked by mortar containing gypsum sand, but only feebly by mortar containing limestone sand alone, or with an addition of gypsum. Lead, on the other hand, is energetically attacked by limestone alone and with an addition of gypsum, but only feebly by gypsum sand mortar. Both metals are strongly attacked by pure cement, but the destructive action is lessened by the addition of sand. Hence zinc should be put in contact only with limestone—carbonate—mortar, and lead only with gypsum—sulphate.

The Oil Works of Canada, Limited, have opened an office and factory at 29 Prince Street, Montreal, to manufacture the Hvid type of oil engine. M. L. G. Vincent is the managing director.



MARKET DEVELOPMENTS

Buying is on a More Generous Basis Now

Many Lines Represented in Inquiries and Business Now Being Booked—Prices Show a Decided Tendency Toward Higher Levels

THERE is a steady improvement in machine tools and supplies, and there is more general buying of steel and kindred lines. All through the summer season business has been showing a betterment, and there are indications that it is going to continue.

One thing seems to be quite certain, and that is that the lines represented that are buying now are well distributed, indicating a much more general activity than has been noted for some time. Several very good inquiries are in from the mines this week, while the railroads, automobile and agricultural industries are also buying.

Price lists for the most part remain the same. There can be no dodging the fact that the tendency is upward, and that a new list for certain kinds of steel products will likely be out before long. Warehouse interests in several instances have been advised to protect themselves against any outstanding quotations they have on present figures, and to close the business or cancel, as new lists are on the way.

It is become more evident daily that those who have stayed out of the market, hoping for better prices on machinery, or on raw material if such material came from the steel market—are in for a disappointment. The lower price has not arrived, nor is there any indication that it can for a long time to come. The fact that prices are stronger and likely to increase is a sign in itself that buying will be brisk for some time to come, fearing that further advances may be coming.

The scrap market shows even greater strength than it did a week ago. The scarcity of heavy melting is becoming more marked, and it may be that better prices will have to be offered to bring out any of this material. This same condition is developing to a marked degree in United States, where it is recorded that heavy melting is selling for more than pig iron, certainly an unusual situation, due, no doubt, to local conditions.

SELLING BECOMES MORE GENERAL IN MONTREAL MARKET LATELY

Special to CANADIAN MACHINERY.

MONTREAL, Aug 7.—While the outward signs of business do not appear to show any marked degree of activity, the reports that can be gathered from different sources would indicate that industrial life is gradually assuming a more staple character. A feeling of confidence seems to be taking hold more rapidly, but there is still much room for improvement. However, it cannot be expected that sudden developments should take place and while business is gradually increasing there are many who claim that existing circumstances prevent the carrying out of enterprises that would be possible if industrial conditions were more favorable. The steel trade here continues steady, but does not show the increase that has taken place in other directions. Machine-tool dealers are reporting comparatively good sales, and it is interesting to note the gradual increase in the enquiry for new equipment. Many users of machine tools have been waiting for an easier market, but are beginning to realize that there is a probability that quotations will go above the advances that have been made recently. Metals are still moving freely, and the situation in this respect would indicate that further activity might develop. Old material dealers that have been laying in stocks may reap the result of their foresight in the coming weeks, as the continued strength and good demand has stimulated buying to some extent.

Steady Growth in Metals

"The better demand that has developed for all metals during the past few weeks would seem to prove that business, generally, is returning to a more normal condition. Consumers that have apparently been waiting an easier market in which to purchase metal have been disappointed, and are now realizing that a marked decline in prices is very unlikely. In fact, our impression is that the present is a good time to buy, and many consumers are seeing the advisability of covering their requirements, not only for the present, but future buying is in larger volume. The present market is quite strong. We are not making advances this week on anything but tin; this market has become stronger and we are asking 59 cents per lb. Copper is going better, and also spelter. Brass mills are taking considerable metal." This statement by a dealer here, reflects the better tone of the market and the steady character of the business now being done. The dealer remarked that the German interests have not yet traded heavily in American copper, but believed that feelers were now out for considerable tonnage.

Better Machine-Tool Demand

That general business conditions are nearing a more progressive stage is shown by the optimistic reports of machine-tool dealers. The enquiries that are coming in are not for large single orders, but the sales are more numerous, due to the fact that a greater number of buyers are coming into the market. In the larger number of cases the purchasers are for one or two machines, but it is in the quantity of such orders that gives to the market the feeling of better times. As one dealer remarked: "We are looking forward to a good fall in respect to the sale of machine-tools. The fact that we are now selling more new tools would indicate that many are giving up the idea that prices on tools will come down. Second-hand equipment is still going good, but the sale of new machines is steadily growing. Grinding machines and millers are the best sellers." There is no doubt that many industrial strikes have affected the activity in machine-tools, but with settle-

ments being made or adjusted, the probability is that an increased demand for tools will follow.

Scrap Sales Still Good

Scrap sales for the week have been on a par with that of the previous week, but the inquiry is good and the consumers are buying freely, but sales for future needs are seldom made. The better business at present is being done in the non-ferrous scraps, steel purchases being on a comparatively light basis. "Our sales for the week have been good," said one dealer, "and the outlook appears satisfactory, but many consumers hold up their hands when future buying is suggested. We have had a few fluctuations in prices during the week, but those listed are nominally correct."

BUYING BECOMES MORE GENERAL NOW

TORONTO.—A large number of industries are represented in the purchases that are being made this week. There has been a gradual improvement in this respect, and each week sees lines coming into the buying list that have been absent for some time. This may be due to business that is pressing, or to the fact that the market all around for machinery, supplies, or steel is stronger, and increases are being made.

The scrap metal market continues strong, and is still marked by a real and acute scarcity in some lines, particularly heavy melting steel. There does not seem to be much of this material to dispose of, and there is also a scarcity of machinery scrap, the demand for this latter being brisk, with the offerings correspondingly poor. There is some speculation as to whether much of these "wanted" metals are being held back for still greater increases. It would appear that there should be more of this material in the country. It may be that labor is not available to bring it out, or that the price is not tempting enough, but the fact is that it is not making its appearance.

The Steel Market

Seamless steel tubes are about due for an increase, although the new prices were not announced yet, but the warehouses are calling in quotations that were made some days ago, and which have not been closed with. The increase will probably be about 2½ per cent., and the only good reason that CANADIAN MACHINERY can find for it is that there is a great demand for tubes just at this time, and many of the mills are booked well into the future.

Sheets have gone up at the mills in some places, although there has been no increase at the warehouses. Advice received by CANADIAN MACHINERY on the sheet situation this week states: "We believe that all of the mills are entirely sold up for third quarter delivery, and we know of no manufacturer as yet quoting jobbers for shipment throughout the fourth quarter." The same advice goes on to state that "Further advances in prices both upon sheets and tin plates may be expected within the next few days."

There seems to be a difference of opinion in the market regarding the plate situation. Advices from very reliable sources continue to refer to plate as the weak spot in the steel situation, while others point to the fact that operations are gradually approaching some 70 per cent. capacity at many of the mills. There was one order for some three hundred tons that went to a Cleveland mill a few weeks ago, and the impression seemed to be abroad then that the selling agency in this country had broken the 3.65 price. However, it turns out now that such was not the case, and the business was secured because the mill in question had a more advantageous lake and rail rate than the Pittsburgh mills. The price was 2.65 f.o.b. mill. One dealer this morning was willing to stake his reputation on the fact that a higher schedule for plate would be announced inside of a month. This hardly seems likely, as there is a very large plate capacity in the steel centres now, and it can take on a lot more business before coming to the point where capacity will be in sight.

Drills Are Cheaper

A ten per cent. reduction was announced in Canadian drills this week, high speed and carbon. Buying of supplies is improving. Dealers in this district are already beginning to get some of the daily breakage in the way of business, and this has been entirely absent for several months in most shops, as there has been little work.

POINTS IN WEEK'S MARKETING NOTES

Instead of dropping off, as is usual in the hot weather, buying at the steel mills is actually showing an increase.

A ten per cent. reduction is announced by makers of Canadian drills.

Steel tubes, seamless, advance slightly, about 2½ per cent.

Machine shop supply trade is improving as more shops are coming into active operation following settlement of the strike.

The Steel Corporation is not favorable to price advances this year, although the steel market all through is much stronger.

Several independent mills have advanced prices $2 a ton on black sheets and $4 a ton on galvanized.

Dealers who bought shell steel scrap some weeks ago above the market figures at that time can now turn around and sell at a profit. Most of them are "sitting tight" and little heavy melting is coming into the market.

SCRAP BROUGHT MORE THAN PIG

THE scrap market shows great activity, with higher prices all round. No. 1 cast scrap has sold higher than pig iron in one district. Following are reports from U. S. points:

PHILADELPHIA.—Steel scrap has been quiet in the domestic market, but a very large sale of heavy melting steel for export has been made. 2,000 tons stove plate was sold to a New Jersey interest at $21, delivered.

BOSTON.—Dealers are buying any lots that come on the market, and prices are high. The slight falling off in buying by consumers had no effect in lowering prices. Machine shop turnings have brought $10.50 delivered, and $21 has been offered for malleable scrap.

NEW YORK.—Fairly good demand in all grades, with prices steady and tending upwards, is the market condition here. $21 delivered has been reported for heavy melting steel for Pittsburgh, but the local price is around $15.50 to $16 f.o.b. New York.

PITTSBURGH.—Dealers are holding stocks for higher prices, it is pretty well believed, and heavy melting steel may see $25 before long. Some small orders have been closed at $22 for this grade. Machine shop turnings are quoted at $14.50 to $15.

BUFFALO.—Heavy melting steel is in active demand, and dealers are holding their stocks. Outside districts are offering higher prices than local consumers will meet. $22.50 delivered has been offered for heavy melting by valley mills.

CLEVELAND:—Trading is better, and both scrap iron and steel are showing strength. Heavy melting steel has advanced $1, and is quoted at $21 to $22. Demand for all grades of scrap is strong, steel rails and car wheels going up about 50 cents.

CHICAGO.—No. 1 cast scrap has sold here at higher prices than pig. $28 per ton has been secured for this grade for fair sized quantities. Re-rolling rails and stove plate are almost unobtainable. Railroad offerings are light.

CINCINNATI.—Most grades are firm, greater activity having been noticed in the cast iron and steel scrap market lately. There is some talk of a scarcity of scrap should the melt increase. The ordnance department is expected to offer some scrap shortly.

ST. LOUIS.—Dealers are piling up material in their yards, and are not keen about selling at present prices. Re-rolling rails have gone to $28.50 and $29 per ton. Stove manufacturers are operating at a good capacity, and prospects for fall and winter are good.

USED TOOLS WERE NOT MUCH BELOW PRICES THAT WOULD SECURE NEW ONES

Special to CANADIAN MACHINERY.

NEW YORK, August 7.—For the first time since the financial position of the railroads became so critical, one of the roads, the Cumberland Valley, a subsidiary of the Pennsylvania, has come into the market with an expenditure of about $100,000. Orders were placed with the Philadelphia dealers for about 25 tools. The list was issued several months ago, and the trade has begun to think, that, like many other recent railroad inquiries it would come to naught. The purchase is encouraging in that it shows the need of the railroads for new and modern equipment, and further shows that funds are forthcoming when the Railroad Administration is definitely persuaded that the need is an urgent one.

In the absence of large lists in the East, business in machine tools during the past month has been confined largely to small lots, but it appears from the reports of some sellers as to July business that the aggregate of these is better than has been supposed. In fact quite a fair proportion of machine-tool buidlders are now in a fairly comfortable position as to orders, while a few are downright busy. Compared with pre-war records a very satisfactory machine-tool business is being done; the fact is, however, that many machine-tool plants so greatly increased their capacity during the war that they are figuring on total capacity rather than on the business they did prior to war times.

Auto Business Buying

Some of the largest orders continue to come from the automobile industry, as, for example, a $500,000 contract for automatic machines received by a New England builder from a Detroit automobile company, but thereis an increasing amount of business from other industries. A Chelsea, Mass., shipyard has bought a list of plate-working machines; a New York concern has expended $50,000 or more for plate-working machines and tools for a ship repair plant, and new equipment has also been purchased by the Bethlehem Shipbuilding Corporation for its Sparrows Point, Md., yard. The Bethlehem Steel Co. has been an active purchaser of various kinds of equipment for its steel plants. Sentiment in the steel trade clearly indicates that, barring labor troubles, this fall and winter will be unusually active.

The Export Business

Export business is in fair volume. Chinese and Japanese inquiries have appeared in the market, chiefly for large tools for railroad and shipyard work. The Standard Oil Co., of New Jersey, had revived an old inquiry for about 75 tools for Rumania. The list was issued months ago, but no action has been taken. It is expected, however, that purchases will now be made very shortly.

August starts out under good auspices. The trade has just had a good month, and if customs of former year prevail there should be increasing activity as the autumn months approach. Certainly sellers are on a firmer foundation for there appears to be no prospects of further weakening of prices, but on the contrary the indications point the other way. Some prices have been advanced and others are likely to follow. Lathe manufacturers have advanced prices from 10 to 15 per cent.; a manufacturer of plate-working machines has advanced about 20 per cent. and a turret lathe maker has put an increase of about 17 per cent. into immediate effect. Some of the prices paid for used tools at an auction sale held recently at the plant of the Standard Aircraft Corporation, Elizabeth, N.J., pointed to a strong condition in the market as they were within close range of the prices now quoted on new tools of the same types.

Some of the second-hand machinery dealers who attended the sale were quite content to look on as the prices being bid by manufacturers who wanted the tools for their own use were above what any dealer could pay and resell at a profit.

BIG PRODUCERS ARE OPPOSED TO HIGHER STEEL PRICES FOR THIS YEAR

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., August 7.—Despite the fact that now is the middle of the midsummer period, almost invariably a very dull one in the steel market, trade conditions are visibly improving. The volume of buying keeps up, if indeed it does not increase, and prices show a stiffening tendency. In this they reflect the heavy bookings all the mills have done. Shipping orders in July, including new orders and specifications against contracts, made a total tonnage fully double the shipments in the month. The only undesirable feature of the market situation is that the buying is poorly distributed among the products. There is too much buying of some products, more than the mills can take are of, and too little in others. Thus the lap weld departments of the pipe mills are sold up to the end of the year and are making five-month delivery promises, while the plate mills are operating at less than half capacity and the rail mills are doing practically nothing except by way of producing rails for export.

Steel mill operations are now estimated at fully 75 per cent. of capacity, based on ingots produced, or perhaps a trifle more. The output for July as a whole will probably show somewhat over 70 per cent., against 67 per cent. in June, and 54 per cent. in May, the month of lowest production.

Steel Price Advances

While members of the steel trade do not disagree with each other as radically, and certainly not as vociferously, as members of the United States Senate, there are very marked divergencies of opinion as to price policies. Some producers are committed to making every price advance that seems feasible, in other words, doing everything "they can get away with," while others regard it as much wiser, and likely to prove much more advantageous in the long run, to hold prices precisely where they are. More than a month ago the United States Steel Corporation, without making any formal or official statement, allowed it to become distinctly known that it was opposed to any steel price advances, this year at least, and that is still very positively the Steel Corporation attitude. It is not alone in this position, there being at least one or two large independent producers that share the view. Just why some independents are so anxious to advance prices is not made altogether clear. They can hardly believe that the steel market is capable of advancing indefinitely from the present level, and present prices are certainly highly profitable to any mill that has full operation. Prices cannot be advanced in any line where there is not full operation. Those who believe in holding to present prices contend that the period of market activity will be prolonged thereby, that price advances will bring the end sooner, and they also contend that an advancing steel market is almost certain to result eventually in higher wages. Mills might have to pay higher wages before they had completed orders taken at the old prices. Rather satirically they suggest that if mills know this, as they should, they had better advance wages at once and then they would have a good talking point—which they have not now—for advancing prices.

The advance in wire products noted a week ago, as made by several producers, is now practically general, in this way, that the majority of independents have advanced their prices while the other independents as well as the American Steel & Wire Company (Steel Corporation) are practically out of the market since they are booking business only from regular customers, and then in quite restricted fashion. This makes the market quotable at spreads, 3.00c to 3.10c on plain wire and $3.25 to $3.50 on nails.

Pipe mills have not advanced prices generally, following the example of the Wheeling Steel and Iron Company, which advanced butt weld 2½ points and lap weld 5 points on July 10, but it is reported that a number of mills are taking business at premium prices, i.e., their regular quotation is the open market but for the delivery that the buyer wants there is a higher price.

Several of the independent sheet mills

have advanced prices $2 a ton on black sheets and $4 a ton on galvanized, and in some quarters it is predicted that eventually all the independent mills will be on the advanced basis. The leading interest has made no advances and shows no sign of doing so, but when importuned by automobile interests to cover them for the first half of 1920 it has made some sales at $5 a ton advance. Apparently it proposed this advance in the first place in order to discourage the automobile trade from buying for so late a delivery.

For all the important steel products there is as much demand as 30 days ago except in some cases where mills are filled with contracts already, and then they are getting good specifications, while in some lines there is heavier demand. Lettings of fabricated steel contracts are making a heavier tonnage almost every week, and are now running at approximately the capacity of the fabricating shops. There is increased demand for merchant steel bars from nearly all customers, and the cold drawing shops are particularly good buyers. They are running full on sizes of 3-in. and less, but at low rates on the large sizes. Forging billets are now moving in a moderate way, mills having sold several hundred tons in the past fortnight, and they state they are obtaining the full March 21 price, which is $51, Pittsburgh, or $12.50 over the regular price of rolling billets.

The pig iron market is strong in foundry grades, but Bessemer and basic are a trifle unsteady. The condition is natural as foundries are running fairly well and want their particular demands, while for Bessemer and basic there is never so much demand in the open market unless the mills are operating very nearly at capacity. There are many large steel interests that make enough iron themselves for ordinary requirements but when they are particularly rushed they have to buy some merchant iron to fill in.

Scrap

The advance in scrap prices, particularly heavy melting steel, has brought the market to a very interesting stage. Sales of United States and Canadian Government scrap were made to dealers in the past few months at prices above the current market, the dealers putting the material into stock, knowing that they could make a profit some time. Now, with ordinary melting steel advanced to $21 to $22, and with special grades like shell steel commanding considerably more, up to $25, those dealers can sell at a fair profit. If they did not sell the market would advance somewhat more as little scrap is being produced, but if any selling movement should start the dealers would probably all fall in line and weaken the market in short order. One dealer in Pittsburgh has sold 25,000 tons in the past few days, but this has not precipitated any general movement, at least thus far. The largest holder is a Cleveland dealer, who has been "sitting tight" up to date.

MONTREAL NOTES OF THE WEEK

Commissioner Ross of the Montreal Administrative Commission has notified that body that he will propose the adoption of a by-law amendment to increase tax on water consumption in breweries, hotels, manufacturing establishments, and other large business houses. The present tax is at the rate of 4 per cent. per year, and the increase, if adopted, will bring this up to 6 per cent. per year, an advance of ½ per cent. per quarter.

There will be no exhibit of the Canadian manufacturers at the Athens fair on September 15. It has been decided the notice was too short for anything but a Government exhibit, but arrangements are being made between the Government and the Canadian Manufacturers' Association for future exhibits to be made at short notice in connection with the Dominion's bid for European trade.

An interesting sight is to be seen in the Montreal harbor just now, in the steamer War Dream, a development of the shipyard of Harland and Wolff. The design was intended to deceive the German U-boats, but unfortunately were not put into commission until the war had ceased. The sides of this vessel, instead of being rounded, are straight slopes, which permits of a plate being easily inserted in case of damage. It gives the stern the shape of a V. She is taking on freight for England.

The Federal housing scheme has again been revived in this district. A further and definite step has been taken in the appointment of a technical commission of three members, who will be associated with Dr. Emile Nadeau, provincial director of housing. The three members that have been mentioned for this work are: F. G. Todd, Montreal, architect; Wilfrid Lacroix, Quebec, architect; and Theo J. Lafreniere, Montreal, sanitary engineer. This commission will act under the direct supervision of the provincial director, and their task will be to draw all the plans for all the municipalities for the various classes of houses that will be built from the $7,000,000 allotted to the Province of Quebec of the $25,000,000 that the Federal Government is loaning for the purpose.

W. J. Sutcliffe has been appointed assistant auditor of freight and telegraph receipts of the Canadian Pacific Railway. He will succeed J. Bonner, who has been retired on a pension. Mr. Sutcliffe has been in the services of the C.P.R. for the past 19 years, starting in the same department in which he is now assistant chief.

Regular passenger service between the ports of Montreal and Havre commenced on the first of this month, when the steamer "California" of the Compagnie Canadienne Transatlantique docked here with 280 passengers. The "California" is a vessel of 9,000 tons, and will leave on her return trip on the 7th inst.

There is every likelihood that a fuel commissioner may be appointed to negotiate with the Americans for the protection of Canadians in respect to the supply of coal for the coming fall and winter. An informal gathering of manufacturers in the Montreal district has taken place to discuss this matter, with the result that a resolution was passed for the petitioning of Ottawa for the re-establishment of a fuel controllership.

After forty years of continuous service with the Grand Trunk Railway, W. D. Hannah, chief fuel inspector of the company, has been retired on a pension. On the occasion of his retirement, Mr. Hannah was presented with a purse of gold by his fellow employees in the stores and purchasing departments.

Heavy rains during the early part of last week was the cause of serious floods in the vicinity of St. George and Beauceville, Quebec, and caused the River Chaudiere to rise considerably, and fears are entertained that floods similar to those of last year will occur should further storms follow.

HAVE PURCHASED THE BIG TRENTON PLANT

Briggs & Turivas, Chicago and New York, dealers in iron and steel scrap and salvage, have purchased from the Imperial Munitions Board of Canada the entire plant and property of the British Chemical Co., Ltd., located at Trenton, Ont. A Canadian corporation under the name of Briggs & Turivas of Canada, Ltd., and capitalized at $1,200,000, has been formed, with main offices in the Canadian Pacific R. R. Building at Toronto, Ont., and a branch office at Trenton, Ont. The property consists of 255 acres and fronts the Trenton River, a navigable stream. Three trunk line railroads enter the plant. The British Chemical Co. was formed and built during the war at an outlay of approximately $8,000,000. The equipment consists principally of two separate and complete sulphuric acid chamber plants, sulphuric acid concentrators, a nitric acid plant, an alcohol rectifying plant, two refrigerating plants, a smokeless powder plant, a complete high pressure fire system, two miles of narrow gauge trackage with electric locomotives and trucks, two boiler houses, electrical equipment, warehouses, storage tanks, administration building, etc. The new owners are as yet undecided as to the extent of the operations of the plant for the future, but it is expected that the powder manufacturing apparatus and equipment, and possibly the nitric acid plant, will be dismantled and disposed of, allowing the sulphuric acid plants to stand.

The Pressure Proof Rings, Ltd., has been incorporated with a capital stock of $100,000, divided into 1,000 shares of $100 each, the head office to be in Sherbrooke, Que. The company will manufacture piston rings, packing, etc.

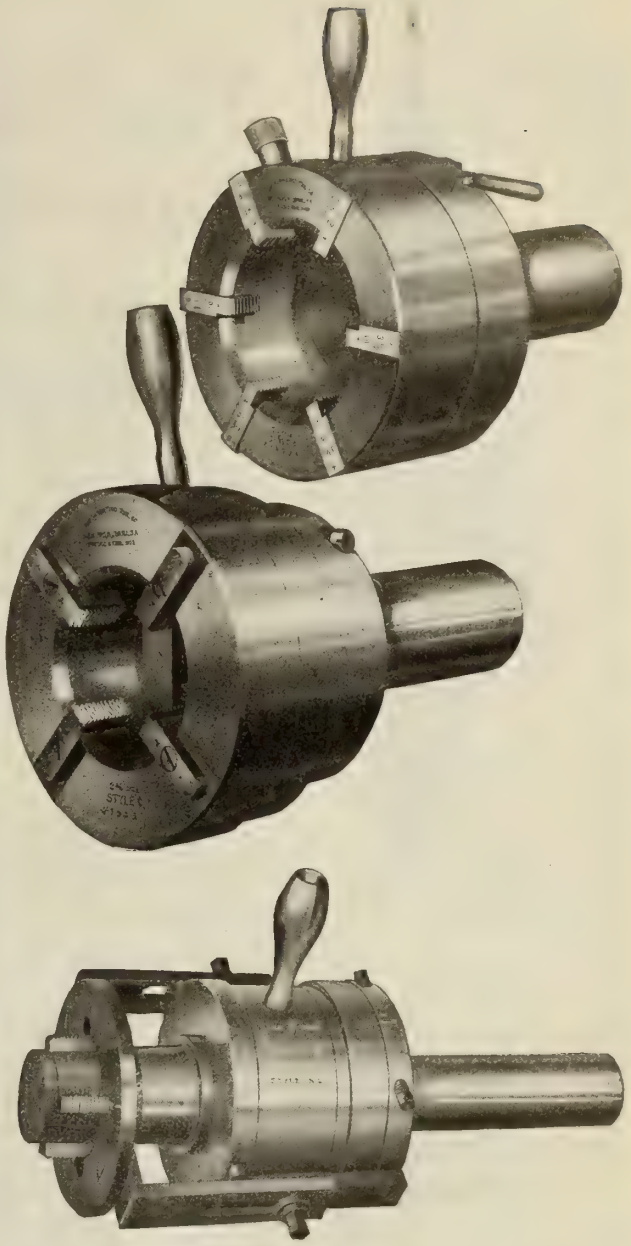
A Good Boon

"Geometric Tools are a boon in our business. Always reliable and sure of turning out a class job; in fact, I don't know how we could secure a decent output without them."

This is what the Works Inspector of a London (England) shop says. He adds that they are making screw and small parts for air craft, and have quite a lot of Geometric Dies in constant use.



Because of the fact that Geometric threading tools are "a good boon" in the thread cutting business, the majority of screw machines and turret lathes are equipped with Geometrics.

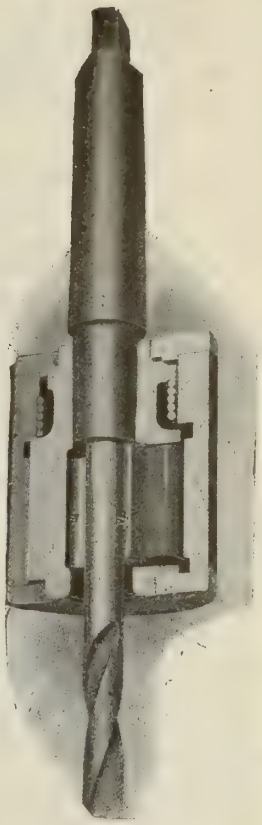
Use Wahlstrom Chucks

POSITIVE DRIVE
AUTOMATICALLY
SELF-CENTERING
NO SLIPPAGE

Aikenhead's

Wahlstrom Attachment



Speed Up Production in Your Machine Shop

Consider the merits of an automatic chuck that keeps the spindle of every drill press running without a second's stop.

Calculate the money value of the minutes saved by the Wahlstrom chuck each time a tool is changed.

The Wahlstrom chuck—not the operator—centres the tool perfectly. It enables the operator to make tool changes in less than two seconds. Spindle of machine never stops. And there is absolutely no delay because of tool slippage. For no tool gripped by the jaws of a Wahlstrom chuck can slip. If the resistance on the tool is great, the holding power of the jaws increases.

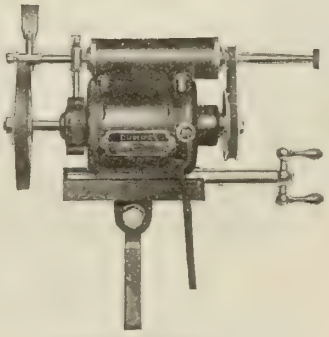
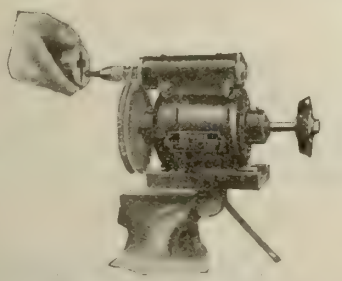
DUMORE ELECTRIC GRINDERS



Invaluable for Accurate Grinding of Tools

These grinders are designed to meet the requirements of the manufacturer who desires a light grinder which will do accurate work, and at the same time does not wish to invest in a large and more expensive tool. The Dumore grinder can be quickly attached to lathes or other machine shop equipment. Their scientific construction entirely eliminates vibration and work done is accurate and free from chatter marks.

Write to-day for descriptive literature.



EQUIPMENT C

Button Die Grinder. Speed, 50,000 R.P.M.

EQUIPMENT A

General Tool Room use. Includes high-speed internal spindle. Reach, 2 inches; speed 30,000 R.P.M.; motor spindle speed, 10,000 R.P.M.

EQUIPMENT B

Deep Internal Work, 10-inch extension arm. Speed, 10,000 R.P.M.

AIKENHEAD HARDWARE, LIMITED

17 TEMPERANCE ST., TORONTO

LOOKS LIKE A HIGHER 1920 PRICE

THE market for pig iron keeps active and prices firm. Buying for 1920 delivery has taken place, at much higher than present levels. Following are reports from various United States points.

CHICAGO.--Repeat orders have been a feature of the market here, one customer purchasing 1,500 tons after making a purchase of 1,000 tons to carry him over the year. An order for 15,000 tons for first half of 1920 has been booked by a leading seller, at $2 per ton over present prices. Most of this was malleable.

BOSTON.—Boston agents report sales amounting to 7,000 tons, not including a 5,000-on order booked direct at furnace for the Crane Co. Some business has been placed for last quarter and first quarter of next year combined, but there is little enquiry for 1920 business. 1.75 to 3.25 silicon iron has been sold for $32 furnace last quarter.

NEW YORK.—The market is strong, with enquiry very active, and sales good. The export market is being canvassed, but high freight rates and unfavorable exchange are against business. A large interest closed an order for 10,000 tons, and is said to be in the market for another 10.000.

PITTSBURGH.—Steel making and foundry grades are being enquired for, and No. 2 foundry has been sold at an advance of $2 per ton, for last quarter. Only one booking for next year is reported, for 8.000 tons railroad malleable distributed between three or four furnaces. Low phosphorus is quoted at $39 to $40 valley furnace for copper-free iron.

PHILADELPHIA. — Business continues brisk, and prices tend to stiffen. The Worthington Pump Co. is enquiring for 7,000 tons for last half and first half. The Roebling Co. bought 10,000 tons among different makers, the price being from $26.75 to $27.75 delivereed.

BUFFALO.--The furnace capacity still available is rapidly being booked up. Next year's business is not being looked for. Enquiries during the week have been brisk, and actual bookings amounted to about 25,000 tons.

CLEVELAND.—Selling has been quite lively, in some cases the business for July having exceeded June, which was a very heavy month. One interest reports sales amounting to 20,000 tons, some for first half next year delivery. Makers generally are not inclined to book business for next year.

CINCINNATI.—Business seems to have been enlivened by the firm stand taken by makers in regard to price. Southern iron has been sold for $28, Birmingham, but $26.75 for prompt shipment on 1.75 to 2.25 silicon can still be obtained.

ST. LOUIS.—Foundries are consuming a large amount of iron, but are mostly covered up to the end of the year, and producers are not offering iron for next year delivery. The signs are for an advance in prices.

BIRMINGHAM.—Furnaces here are being blown in, and production will be increased as fast as possible. Inquiries are good, and makers believe that the output can be sold with little difficulty, and prices will increase.

THE FERRO-ALLOYS

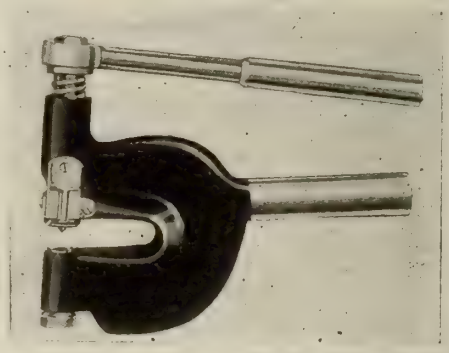
A large industry has grown up within the last fifty years, most of it within the last twenty-two years, which furnishes steelmakers alloys of iron with some of the rarer metals. It is quite commonly known that the addition of these metals to steel greatly improves its qualities for special purposes. These ferro-alloys were originally made in crucible, cupolas, or blast-furnaces, but are now made principally in electric furnaces, and their manufacture is now one of the principal electric-furnace industries. They are of great importance to the steel industry. The steelmaker uses them for one of two purposes: (1) As reagents to take oxygen out of melted steel, and thus ensure sound, solid casting. For this purpose ferromanganese, ferrosilicon, and ferroaluminium are employed. (2) To add to the steel a small or large percentage of the rare metals, ferromanganese, ferrochromium, ferrotungsten, ferromolybdenum, ferrovanadium, ferrotitanium, ferrouranium, ferroboron.

Melted steel, just before it is taken from the furnace, always contains some dissolved oxygen (like the dissolved gas in charged soda water). The addition of a small amount of metal with a high affinity for oxygen removes this element, and makes the casting sound. Manganese (1 per cent. or less) is the cheapest and most generally used reagent; silicon (½ per cent. or less) is more powerful, but also more expensive, and is often used to supplement the action of the manganese; aluminium (0.1 per cent. or less) is still more powerful and expensive, and is used in very small quantities as a final addition to complete the action of the manganese and silicon. All steelmakers use one, two, or all three of these reagents—manganese and silicon in the form of ferro-alloys; aluminium more often as the pure metal, though ferroaluminium is sometimes used.

When a sufficient quantity of the rare metal is added to the steel, it acquires properties different from plain carbon steels, deoxidized by manganeses, silicon, or aluminium. Thus, a very tough, hard steel, such as is used in mining and grinding, burglar-proof vaults, etc., may be made by the addition of 12 to 14 per cent. of manganese. Chromium (2 to 4 per cent.) makes a very hard tool steel; tungsten (15 to 25 per cent.) makes a high-speed tool steel, which, while red hot, cuts iron. Vanadium (0.1 to 0.5 per cent.) makes a very strong steel, which resists shock extremely well, as when used for automobile axles; titanium, uranium, and boron also impart valuable properties. Every one of these materials produces some specific result; sometimes two, three, or four are used for producing a specific combination of special properties. Some of these materials cost 20s. per pound, and special steels produced up to 10s. per pound.—"General Electric Review."

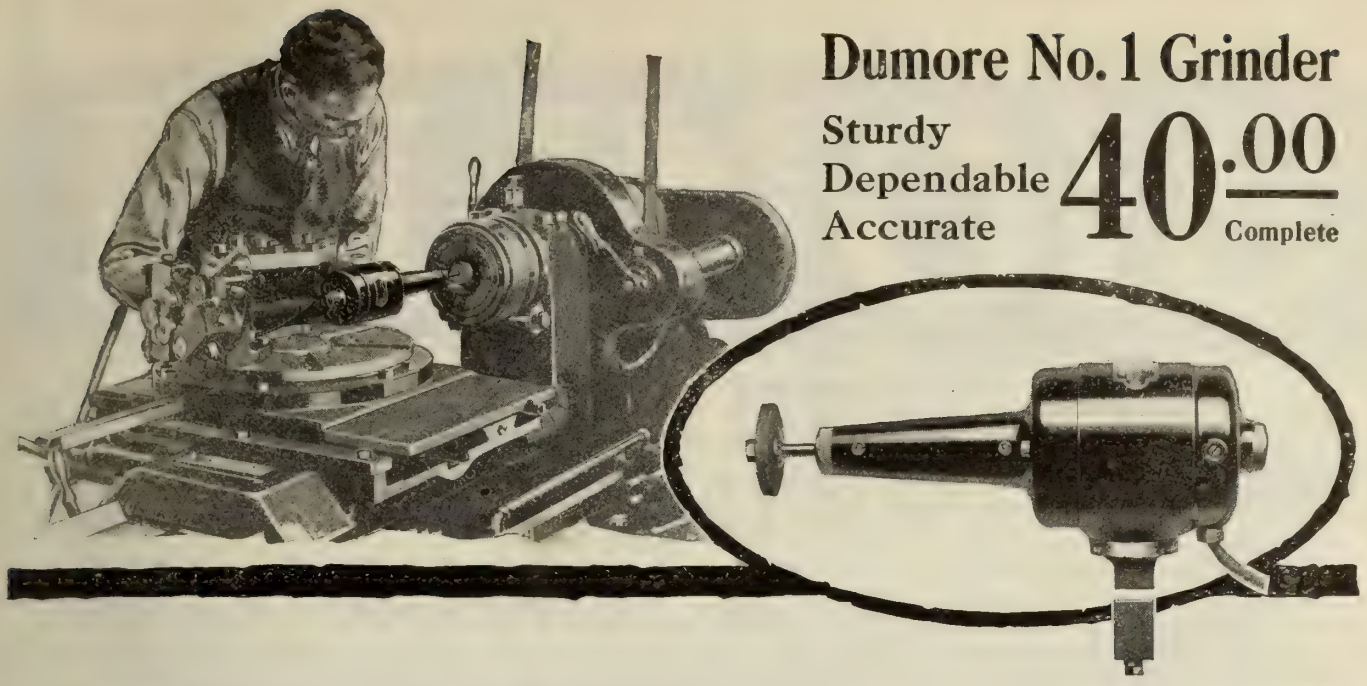
KOCH HAND PUNCH

THE tool which forms the subject of the following description is known as the "Jiffy" hand punch, and it is a recent product of Paul W. Koch & Co., 19 S. Wells St., Chicago, Ill This tool is adapted for use in pla ces where space is limited, and its capacity is for punching holes 5-32, 3-16, 7-32, and 1-4 inch in diameter, in metal up to 10 gage. It will be apparent from the illustration that the punch is provided with a deep throat, and it is equipped with an automatic stripper which is so designed that it does not prevent the operator from gaining a clear view of the punch and work. Several sheets can be punched at one time with this tool. A crowned punch of the floating type is used, which directs power to the center and is so arranged that it will not twist and turn in operation, so that there is little danger of breaking the punch. Also, it is stated that the hole is clean-cut and that there is no tendeny to leave a burr on the metal, half turn of the lever being required to drive it through the metal. This tool is 9-12 inches in length and weighs five pounds.



GENERAL APPEARANCE OF THE PUNCH.

In the power house of the Interborough Rapid Transit Co., New York, is what is claimed to be the world's greatest prime mover. This is a cross compound turbine, consisting of a high pressure and two low pressure elements, the capacity of the whole unit being 60,000 kw. continuously, and 70,000 kw. for one hour. The floor space occupied is 52 x 50 feet, and the height about 19 feet. The high pressure turbine receives steam at 205 lbs. gauge and 150 degrees superheat, and the exhaust is divided equally between the two low pressure turbines. Each element operates at 1,500 r.p.m., driving a direct connected generator of 20,000 kw. capacity, three phase, 25 cycle, 11,000 volt.



Dumore No. 1 Grinder

Sturdy
Dependable
Accurate

40.00 Complete

THERE is no doubt of the value of the **Dumore No. 1 Grinder.** No other tool, at or anywhere near its price, can give a greater amount of actual, accurate daily service.

Because jigs, dies, gages, bushings, etc., will always warp during tempering, thousands of mechanics use the **Dumore** grinder to bring these tools to as close limits as .0001″. Such a degree of accuracy is possible solely because the **Dumore** is perfectly balanced throughout and operates at the correct cutting speed.

We have some very interesting literature for men facing grinding problems —write for it.

DUMORE HIGH SPEED GRINDERS

Brief Bits of News From Many Sources

A considerable vein of pitchblende, from which radium is extracted, has been discovered near Buckfastleigh, in southern Devonshire, England. The ore yields over 26 per cent. of uranium oxide, and the lode will be developed immediately.

* * *

A very effective dust catcher for surface grinders consists of an iron bracket, to which is bolted a broad piece of sheet metal, with a water pan or trough built on at the bottom. A piece of heavy cloth, or burlap, is hung over the sheet-metal surface, long enough to reach down into the water trough. The burlap soaks up the water like a wick, and is always kept wet. Emery dust and small metal particles thrown against it are caught and kept from flying around the shop.

* * *

When the race of an automobile ball or roller bearing works loose, the surrounding metal may become so badly worn that even a new race fits loosely. In such a case the worn surface can be built up with solder until it makes a tight fit, and the bearing can then be forced into position with a hardwood punch. Loose dust caps can be fixed in the same manner.

* * *

Wealthy tourists to St. Moritz, the world-famous Swiss winter and summer resort, may soon be able to make the trip from Zurich in one hour, instead of the seven or eight now required by the railroad. Capitalized at about $100,000, a company has been formed to back the 90-mile airplane line, and has already announced that service will be inaugurated during the year with tickets selling at about $100. Many will doubtless be willing to pay this price, if for nothing but the matchless view of mountains, lakes, and glaciers.

* * *

Liquids and solids do not ordinarily mix, and the idea of combining coal and petroleum to make a new fuel sounds rather chimerical at first. Yet that very thing has been done, and successfully, by pulverizing the coal so finely that it forms a colloidal, or suspended, mixture with the oil. This compound passes freely through all regular oil pipes and burners, so that it can be used for power and heat without equipment change; and it generates a greater heat value than oil alone. Coal dust, passed through a 200-mesh screen, mixed with a little tar in the oil, leaves no deposit even after months. Use of the new fuel in place of fuel oil on sea and land would save millions of barrels of oil a year.

* * *

A newly developed steel that seems particularly desirable for dies, taps, and other cutting tools, changes its form so little during the hardening process that castings have the appearance of smooth forgings, and need almost no machining. The texture is uniform and close-grained, and castings may be subjected to high temperatures without scaling. Because of this heat-resisting property it is claimed that the walls of annealing boxes may be made much thinner with this material, and that the original shape and weight is retained through many more firings than when malleable or cast iron is used.

* * *

Pottery ware which is to be subjected to kiln fire is placed in rough clay boxes, called "seggars." Ordinarily made by hand, these articles can now be turned out by an electrically-driven press, which increases the capacity of a man and helper about tenfold. The operator places a piece of plastic clay in the mold, pushes it under the press, and moves the lever forward. The screw brings the top plunger down, and presses the seggar; after which the machine reverses itself and comes to a stop at the proper height. Pulling the mold back, the operator pushes out the seggar by means of the geared ejector. The helper carries the finished product to the drying room, from which it is delivered ready for use.

Two men could make by hand about 60 or 70 seggars, but it is claimed that with this machine the output may go as high as 1,000 a day. Much coarser materials may be used than with the hand presses.

* * *

A novel kind of lock nut, which cannot be accidentally loosened on the bolt, but is readily removed with a wrench, has been designed by a woman inventor. A recess in the top of the nut is shaped at the bottom like a shallow spiral stairway. The nut is turned onto the bolt, and a short cotter pin is inserted through a slot in the bolt. Tightening the nut engages the pin with the notches or "stairs" of the recess, which position it holds until forcibly disengaged. With the cotter pin removed it acts as an ordinary nut.

* * *

THIS is the season of the year when the $10-a-week chap makes a sensational splash at the $40-a-week summer hotel.

* * *

IN CHICAGO blacks are bowling over the whites, and the whites are asking the blacks to leave the premises feet first with a bunch of flowers on top of the heap. Sort of putting things down in black and white.

* * *

MANY people spend a great deal of time wondering why the Government, or some other organization, does not go ahead and deal with the cold storage. We heard of one man who spent three days going around getting signatures to protest against storing eggs. The same amount of effort, together with a crock and some water-glass, would have given this well-purposed chap a cold storage plant of his own, and would have made the doings of the cold storage people a matter of indifference to him.

* * *

UNITED Mine Workers of America have revoked the charter of District 18, taking in Alberta and British Columbia, because officials have joined in with the One Big Union. Officials of District 18 have for years been eager to grasp onto and embrace anything and everything in the line of radical action. They have succeeded now in getting themselves alienated from one of the most powerful and sanest labor organizations in the continent.

HAVE YOU LOTS OF FRIENDS?

By H. J.

If you have, then all is Jake, as the saying goes.

If you have not—then something is out of kilter.

Is this your trouble?

Are you inquisitive, and keep sticking your nose into other people's business?

Do you repeat all the gossip tales you hear of?

Did you ever haw! haw! at some religious belief you've heard suggested?

Do you carry a grouch around with you?

Have you ever knocked someone, simply because they possessed some quality you haven't got yourself?

Do you tell your troubles, and speak of your aches to every Tom, Dick and Harry that you meet?

Do you try to convince everybody that this old world is all built wrong, and that you've been lost in the shuffle?

If you have spilled any of the above remarks from time to time—no wonder your friends are few.

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

OBITUARY

The death of Capt. Murphy, at the age of sixty years, is reported from Kingston. Capt. Murphy was a son of the late James Murphy of Kingston. He was for many years a pilot on the St. Lawrence.

Mr. Robert M. Cox, of Liverpool, England, and Ottawa, died at his Ottawa residence, 381 Stewart street, in his 83rd year. He had been interested in the lumber trade in the Ottawa district for the past 45 years, and was an esteemed member of a large circle of friends. He visited England for part of each year since he started in business, forty years ago.

PERSONAL

A change in the management of the Union Carbide Company, Welland, is announced. Mr. John White, who has been manager of the Welland plant since its inception five years ago, goes to the company's plant at Sault Ste. Marie as manager. He will be succeeded by P. F. Gormally, at present assistant manager at the Soo.

The Senior Trade Commissioner for Canada and Newfoundland, Mr. G. T. Milne, is being transferred to Havana, Cuba, as commercial secretary to the British Legation in that city. No announcement has yet been made as to his successor.

TRADE GOSSIP

New Waterworks for Chatham.—The present water system of Chatham being unsatisfactory, it has been decided to build a new plant at a cost of $250,000.

Newfoundland Imports Free. — The last restrictions on imports into Newfoundland have now been removed, by flour being restored to pre-war conditions.

Algoma Steel to Extend—The Algoma Steel Co. will spend several hundred thousand dollars in making extensions to their mills, to enable them to manufacture structural steel up to 32 inches.

English Firm For Hamilton.—The firm of Perrits & Spencer, Bury, England, will build a factory in Hamilton at an approximate cost of $600,000. W. J. Westaway has been appointed engineer for the building.

Purchase Coal Handling Plant.—The coal handling plant on the Canadian National Railway terminals at Halifax, has been purchased by the Nova Scotia Steel & Coal Co. from the British Ministry of Shipping.

Chatham Buys Asphalt Plant.—The city council of Chatham has bought an asphalt plant at a cost of $18,000. The plant will be delivered in about five weeks, and work will be immediately started repairing the streets.

Military Hospital Expands.—The Ontario Military Psychiatric Hospital is to have five additional buildings. Two will be for recreation, one for isolation, one for tuberculosis and one for the vocational re-education branch.

New Smelting Plant.—The forthcoming industrial congress at Calgary will consider the establishment of a smelting plant near that city, the new process of smelting by electricity to be employed. Considerable interest is being displayed already.

Strike at Lauzon.—About 900 men at the Davey Shipbuilding Co.'s plant at Lauzon, near Quebec, walked out on strike. The men belong to the International Union, and the strike is for recognition of the Union. The yards employing National Union men are still operating.

To Inaugurate Sunday Service.—The Grand River Railway Co. will commence a Sunday service covering all points on the line. This will give a two hour service connecting Kitchener and Hespeler, and the C.P.R. at Galt will give connection with the Lake Erie and Northern Railway to Port Dover.

Electrifying Montreal Harbor.—The Montreal Harbor Commissioners have awarded contracts for material required in the electrification of the railways on the wharves. Work will be started as soon as material is available. A generator set will have to be installed, the rails bonded and poles and wires erected.

Collingwood Strike Over—The Collingwood Shipbuilding Co.'s men, who have been on strike for the last two weeks, have returned to work. The men went out owing to the dismissal of some of their number who failed to turn to on July 12, in defiance of a notice that any man absenting himself on that day would be dismissed.

Openings in South Africa.—There are good opportunities for Canadian manufacturers to get markets in South Africa, according to Mr. S. P. Morgan, of Cape Town, who is now in the country. South Africa imports nearly every line of goods that Canada produces.

Credit Company Appoint Agents.—Messrs Weber Bros., McLeod block, Edmonton, have been appointed agents of the Commercial Credit Co. The company, which is an old established organization, is engaged in financing sales of tractors, trucks and autos on a time basis.

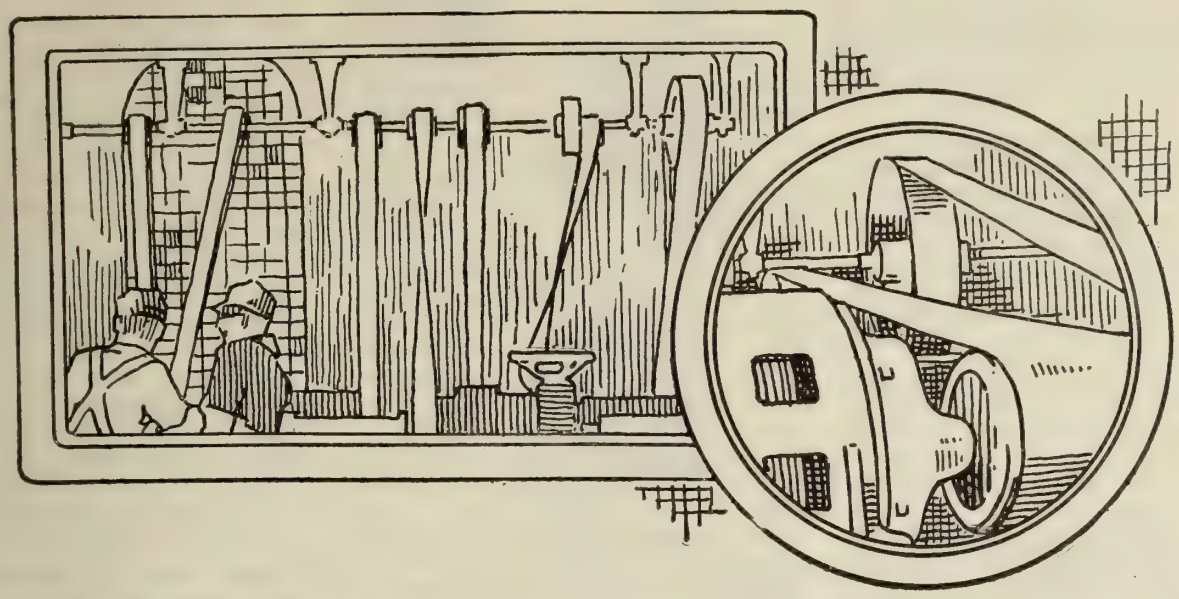
Manufacturers Want Controller.—At a meeting of manufacturers from the Montreal district, the appointment of a fuel controller to negotiate with American authorities for the procuring of coal for Canada at reasonable prices was discussed. The feeling was that the coal situation was very serious, and if factories were not to be shut down next winter, every effort should be made to get coal now.

New Industry for Hamilton. — The Carr Fastener Company of Boston, Mass., are to open a factory in Hamilton. This firm are said to be the largest manufacturers of fasteners in the world. The Hamilton branch will be known as the Canadian Carr Fastener Company, and will be probably capitalized at $250,000. Two and one-half acres of land on Gage avenue have been purchased.

U. S. Firms Looking to Canada.—A large number of American firms have been communicating with the Alberta Industrial Congress, Calgary, on the subject of locations for Canadian branches. Among these are the National Cycle Manufacturing Co. of Bay City, Mich.; the Marchant Calculating Machine Co. of Oakland, Cal.; Edgar M. Moore Co. of Pittsburgh; Cardwell Machine Co. of Richmond, Va., and many others.

Heavy Shot at Chippewa.—A dynamite charge that cost between $4.000 and $5,000 took place at Chippewa recently. The amount of dynamite used in the blast was in the neighborhood of ten tons. It was used in opening up a large section of rock in the forebay of the new development canal above Queenston.

Increase in Receipts.—The customs receipts on imports from the United States show a large increase in the last month, according to the figures issued from the Customs Office. The actual amount for the month is $3,083,243, against $2,698,513 for July 1918. Mr. J. H. Berram, collector for the port of Toronto, stated that it was the biggest month ever known at this season of the year.



Low Up-Keep Cost of Dominion Friction Surface Belting

Cost of maintaining equipment in the average plant is seemingly so small when compared with other costs that it is seldom considered seriously, but when totalled at the end of five years, represents a far greater expense than actual necessity demands.

Maintenance of belting is in itself an important item, because each repair means idle employees, idle machines and less production, the total cost of which is often greater than you would pay for better belting.

Dominion Friction Surface Belting is built for "service first" that its long, continuous performance may eliminate the necessity for repairs and replacements.

But it gives an added service in conserving power—the rubber that goes into it is a special friction compound that prevents practically all slipping on the pulleys even under quick load changes.

Our belting experts are ready to help lower your maintenance costs on belting and can suggest changes that will lower your production costs.

A phone, wire or letter to our nearest service branch, places at your disposal, without obligation or charge, not only their services but the entire facilities of the oldest and largest rubber organization in Canada.

To Use Dominion Lumber.—The heavy stocks of lumber purchased by the British Government during the war are to be shipped over to England as fast as space can be provided for them. The material will be used for house building, the lack of houses being one of the principal causes of industrial unrest.

A Fortune in Oil.—Mr. Kenneth Johnston, a former Sarnian, but now of Buffalo, is the inventor of a lubricating grease, which has been taken up by one of the largest oil companies in the United States. The sum paid to Mr. Johnson for his invention is said to be $600,000. He is a veteran of the South African war.

Strike is Settled. — The Polson Iron Works have affected a settlement with the various unions employed by them, an dthe me nhave returned to work. The men withdrew their demand that the company should recognize the Marine Trades Federation and the Marine Council. A 47 hour week has been conceded and wages raised.

Better Output for Sydney.—The output of coal for the month of July, as shown by the records, has increased at Sydney, C.B. The highest output was obtained by the Florence Colliery with a figure of 16,000 tons, the Princess Colliery coming next, with 13,000 tons. Scotia had a decrease but this was

Newmarket Boiler Explosion.—At the inuest into the boiler explosion which caused the death of five persons recently in Newmarket, evidence was given to the effect that the water used in supplying the boiler was high in sodium carbonate. The analysis of the water coincided with that of the water in other districts where the embrittlement of plates by the action of sodium hydroxid has occurred. The water is from an artesian well on the premises. The ton supply and ahe Office Specialty Supply Co. suply were found to be free from sodium carbonate.

Locating in Hamilton.—The Carr Fastener Company of Boston, Mass., the largest manufacturers of metal fasteners in the world, have completed arrangements for the immediate establishment of a large Canadian branch of their industry in Hamilton, Ont. A two and a half acre site in the heart of Hamilton's manufacturing district has been purchased, and building operations are to be commenced at once. The Carr Fastener Company is capitalized at a quarter of a million dollars, and the buildings to be erected will cost in the neighborhood of $100,000. The Canadian plant will give employment to upward of 200 hands almost immediately, and it is expected that this number will ultimately be increased to 400 or 500. The Carr Company are the manufacturers of the "Lift the Dot," "Durable Dot," "Voltex Dot" automobile fasteners, as well as the "Common Sense" and other lines. In addition to supplying the Canadian automobile and other trades from Hamilton it is the company's intention to have its Canadian plant supply the export trade. Building operations are to be rushed, and the company expects to be manufacturing in its Hamilton plant before December 1.

Municipal Power for Port. Colborne.—Port Colborne decided by a vote of 141 majority to purchase the distribution system of the Ontario Power Company in Port Colborne.

Record Ship Deal.—What is probably the largest sale of ships ever recorded took place when the U. S. Shipping Board sold one hundred steamers built on the Great Lakes during the war for $8,000,000. The purchasers were the Anderson Overseas Corporation of New York. Delivery of the ships will be commenced early in August and proceed at the rate of six or more per week till completed.

Longest Bridge in the World.—A bridge is under consideration between Windsor and Detroit, which will be the longest in the world if erected. The length would be 2,500 feet, 1,000 feet longer than the span of the Brooklyn Bridge. Mr. W. H. Adams, the engineer for Detroit, informed Mayor Winter that the cost of such a suspension bridge would exceed the cost of a tunnel.

Parrsboro.—The schooner, Jennie V. Merriam, was launched from the Port Greville yard of George Wagstaff. She is a fine tern schooner of 454 tons register and is classed for thirteen years in Bureau Veritas. She is fitted with power for hoisting sails and anchor, and is lighted throughout with electric light. Greville for England. Mr. Wagstaff has another schooner under way for other owners.

C. M. A. Meeting.—The Canadian Manufacturers' Association, Maritime branch, held a meeting at Bathurst with President Angus McLean in the chair. A delegate in the person of H. R. Thompson, the secretary, was appointed to attend the trades congress at Calgary next month. It was decided to approach the Provincial Government with a view to having a similar congress for the Maritime Provinces next year. The Trade and Commerce Department will be requested to arrange for visiting British journalists and other British delegates visiting Canada to call at the commercial centres of the Maritime Provinces. through having three or four idle days due to an electrical breakdown.

INCORPORATIONS

The Merchants Realty Corporation has been incorporated with a capital stock of $2,000,000 in 20,000 shares of $100 each, with head offices in Montreal, to carry on a general real estate business.

The Canada Stoker Co., Ltd., has been incorporated with a capital stock of $40,000, divided into 400 shares of $100 each, the head office to be in Galt, Ont. The company will carry on a general business.

The Phoenix Construction Co. has been incorporated with a capital stock $100,000 in 1,000 shares of $100 each, and head office sin Montreal. The company will carry on business as manufacturers of metal products, etc.

The London Clay Products Ltd. has been incorporated with a capital stock of of $50,000 in 500 shares of $100 each, the head offices to be in London. The company will manufacture all kinds of sewage pipe, tile, etc.

The charter of the Ames Holden Mc Cready Co. has bee nextended to include the promoting and holding of shares in any subsidiary or allied company with similar objects, and to finance and generally assist or guarantee the performance of contracts by any such company.

A hardening solution for concrete floors that prevents dusting, says "Concrete" is made from sulphate of alumina and acidulated water. To 10 gallons of cold water add 1 fluid ounce of sulphuric acid. Heat the liquid to boiling point and stir in 25 lb. of sulphate of alumina, then let the solution cool and strain. The concrete surface to be treated must first be swept and thoroughly washed. After drying, the hardener is put on in four applications of varying strength, ranging from 30 per cent solution and 70 per cent. water, up to 100 per cent. solution. The above quantity suffices for the complete treatment of an area of from 50 square yards to 100 square yards. depending upon the porosity of the surface treated.

The Navy Department has adopted an audio frequency signal for aviators which will enable them to land with safety in a dense fog or in the dark. This system of audio transmission which has been perfected has played a conspicuous part in the war and is now being applied to the uses of peace. It will be of advantage to navigators finding their way through fog into port, as well as to navigators in the air. The difficulties encountered because of fog in the recent transatlantic flights of the NC-4's and the Vickers-Vimy airplane demonstrates the need of just such a device.

RECLAIMING TOOL STEEL

All the tool steel over the entire Atchison, Topeka & Sante Fe Railroad is reclaimed, all such steel being returned to the Topeka shop for general inspection, the portion considered serviceable being held in reserve to be made up into small tools. The practice with regard to short lengths of high speed steel is to make tips for lathe and planer tools, although a certain part can be used with patented tool holders. The tools on which the high speed steel tips are applied are of ordinary tire steel. The tips are faced with Norway iron, and welded to the recessed tool ends by the oxy-accetylene process. These tools are said to have proved very satisfactory in service, and made possible the continuous operation of many of the tools which would have had to close down for want of the tool steel which was difficult to secure under war conditions.

TENDERS

The Ontario Department of Public Highways is calling for tenders, which must be delivered not later than Friday, August 8, for the construction of substructure of Odessa bridge. The work consists of concrete abutments, roadway and sidewalk floors, and other necessary work in the building of a bridge over Mill Creek in the village of Odessa.

The Board of Control, Toronto, is calling for tenders for the erection of partitions, etc., in the Rendering House at Toronto Municipal Abattoir, to be addressed to the chairman, Board of Control, not later than August 5. Plans and specifications can be obtained from the city architect, City Hall.

The township clerk, London, will receive sealed tenders up to noon, August 4, for the excavating of Oxbow Creek drains, estimated cost about $10,000. Plans and specifications can be obtained from the Township Clerk, London.

The Board of Control, Toronto, require tenders for all trades in connection with the building of an implement shed at the Men's Municipal Farm near Thornhill, Ont. Tenders addressed to the Chairman, Board of Control, will be received up till Tuesday, August 12. Plans and specifications can be obtained from the City Architect, City Hall, Toronto.

The Department of Public Highways will receive tenders up till August 19, for the following: Construction of concrete structures on the Provincial Highway from Cobourg to Port Hope. The construction of substructure of Pickering bridge, including abutments, roadway and sidewalk floors. Plans and specifications ca nbe obtained from the office of the resident engineer, Port Hope, of the office of the Department, Toronto.

The Department of Public Works will receive tenders till August 5, 1919, for the eastern wharf at Grosse Isle quarantine station, county of Montmagny, Que. Blue prints can be obtained from the Department of Public Works, Ottawa.

Tenders for the construction of the Walkerville sewerage pumping station will be received by the Essex Border Utilities Commission up till August 12. Plans and specificatons can be obtained at the offce of the commission, 14 Victoria block, Windsor, Ont.

Canadian National Railways will receive tenders till August 9, for the erection of a station building at Chicoutimi. Plans and specifications can be seen at the office of the divisional engineer Montreal, Que., or the district engineer, Champlain Market, Quebec.

MARINE

Kingston.—The steamer Phelan went aground at Fraser's Shoal, below Cardinal, and the Donelly Wrecking Co. were requested to send a tug to her assistance.

Victoria.—The third ship of the Foundation Company's building, known as Hull 209, has undergone her steam and endurance trials successfully. The contract speed for these ships is 11 knots. Hull 216, which completed her trials recently, has been handed over to the French crew which were sent out for her.

Montreal.—Canada now has seven ships in commission, and thirteen more will be ready this year. Those already in commission are engaged in the North Atlantic and West Indies trades. These ships up to the present have been employed at profitable rates, and there is no fear that for some time to come they will have difficulty in obtaining remunerative charters.

Collingwood.—After four years' war work the Government steamer "Bayfield" has returned to Owen Sound. She has been employed during the war in Halifax on patrol work. The steamer is in charge of Capt. Nat Barret, of Owen Sound, while Mr. John Nesbitt, of the same town, is chief engineer. After overhauling and repainting she will go on survey work on the Great Lakes.

Port Arthur.—The "Canadian Trader," the first of the new Government freighters built at the Port Arthur Shipbuilding Company, sailed for Montreal in command of Capt. J. H. Foote. She will load in Montreal for Cuba, which she will take to Liverpool. After this voyage she will be placed on the Jamaica to Liverpool sugar trade. Mr. Thompson will sail as a guarantee chief for six months.

London.—There will be no attempt on the part of British shipowners to rival the proposed 1,000 feet liners of the American Shipping Board. The tendency is to build vessel of moderate size and speed, and more of them, in an endeavor

to catch up with the shortage. To build another "Aquitania" would cost more than double the amount that vessel cost.

Cleveland.—Freighters are now experiencing less difficulty in getting cargo for the down trip. Very few are coming down light, although there is plenty of tonnage offering. The coal trade shows no change from the conditions prevailing over the last three weeks, and there is more tonnage offering than actually required. Some mines are not working on account of a shortage of cars.

Bridgeburg.—The second vessel built for the Imperial Munitions Board at the Canadian Allis-Chalmers shipyard at Bridgeburg, was successfully launched in the presence of a large and distinguished company. Mrs. Wallace Nichols acted as sponsor. The vessel was named "War Vixen." Her sister ship, "War Magic," was launched a short time ago. They are built to the classification of 100A1 at Lloyds.

Toronto.—The Bishop Navigation Co. is making a bond issue of $1,000,000, the money being required for the steamer "Iver Heath," which is to be engaged in ocean shipping. The ship is valued at $2,109,000, and the promoters estimate that the net earnings for the next six months will be $360,000. The vessel is now at Halifax, where she is being rebuilt to the highest classification of Lloyd's register. She was built in 1901. A. E. Ames are handling the bond issue.

Port Dalhousie.—The port received a visit recently from the Canadian Government steamer "Concretia," the only reinforced concrete vessel built in Canada. She is employed by the Government in supplying the lighthouses with oil for their lamps. She is of 320 feet in length, 22 feet beam, and depth 12 feet. Her speed is about 9 miles per hour. An interesting feature is the lighting arrangement, gas being the medium employed. This is stored in a tank in the

Toronto.—The "War Algoma" was launched from the yard of the Polson Iron Works with appropriate ceremony, the christening being performed by Mrs. Dingman, wife of Major Dingman, of this city. The "War Algoma" was the 149th vessel to be launched from the yard, and the 150th is on the stocks and will be launched shortly. The "War Algoma" is a full canal-sized vessel, being 261 feet overall by 43 feet 6 inches by depth moulded 23 feet. She is equipped with triple-expansion engines and Scotch boilers, the working pressure being 180 lbs. per square inch.

Vancouver.—The Pacific Steamship Co.'s wooden steamer, "Admiral Knight" was burned to the water's edge, and left a charred derelict off the mouth of the Fraser River. Her crew were rescued by the Princess Victoria, bound from Victoria to Vancouver, and landed at Vancouver. The crew consisted of 23 men, and all were gotten off safely. The cause of the fire is unknown, but the blaze started in the engine room. The wooden construction and the oil fuel

made fighting the flames an impossibility. The crew lost all of their belongings, and the pilot even had his license burned.

Victoria.—Victoria is looking forward with great pleasure to the renewed activities of the dockyard at Esquimalt, with the advent of the North Pacific squadron. There is no doubt that now the menace is past the fleet will be spread over the surface of the globe, and the naval stations that were reduced to skeleton propositions during the war will once again be put on a full working basis. Bermuda and Halifax on the North Atlantic and Esquimalt on the North Pacific are probably the best examples of this. The United States navy will also maintain a fleet on both oceans, and the result will be a large measure of prosperity and fuller social life for the cities within their purlieu.

Port Stanley.—The inauguration of the steamer service between Cleveland and Port Stanley was attended with several undesired features. The "Theodore Roosevelt," a 22-knot steamer, arrived from Cleveland with 1,500 passengers, and reached the Government wharf in safety. It was when she tried to get away again that the trouble started. She tried to turn at the dock, but her stern grounded on the undredged channel and she had to give up the attempt. In trying to get out stern first the vessel was blown by the stiff breeze up against the old pier. Trying to clear this her forward end stuck in the mud. Finally she was towed out into clear water by a tug, not before breaking a few piles from the old pier by trying to make fast a rope to them. The American passengers asked earnestly from the Canadians on the quayside if this was really the finest harbor on the Canadian side, as advertised.

London.—The Board of Trade announce the awarding of the silver medal for gallantry in saving life at sea to the following: Capt. E. C. Perry, Temporary Skipper Martin Dalton, and Seamen Harold Clouter, Charles W. Penney, Adolphus Morey, Daniel Ralph and Michael Whelan, and the bronze medal to Chief Engineer Robert Pierson and Seamen Mathew Shanahan, Patrick Gallagher, George Westcott and Joseph Budden. The occasion when the services were rendered by these men was when the steamer Florizel of Liverpool stranded on the Newfoundland coast about 15 miles N.E. of Cape Race. A heavy sea was running, and in response to wireless calls for assistance, several vessels arrived from St. Johns but were unable to approach the wreck till the following day. They started at daylight and had all the survivors taken off the wreck by 8 a.m. The rescue had to be effected by means of dories, and it was in performing these rescues that the men mentioned above displayed great bravery and saved many lives.

The MacLean Business and Class Publications in Canada

TO SELL or buy from Canada such lines as machinery, hardware, food products, dry goods, books and stationery, paper, printing machinery and supplies and general merchandise of almost every description, raw or manufactured, use or consult the MacLean Business and Class Publications, as per list below. For special information, write the publishers. Concerning the quality of the MacLean publications let this copy of CANADIAN MACHINERY which you hold in your hands speak for all. The MacLean list of 15 publications is as follows:

THE CANADIAN GROCER (Est. 1886)
HARDWARE AND METAL (Est. 1889)
DRY GOODS REVIEW (Est. 1889)
MEN'S WEAR REVIEW (Est. 1898)
CANADIAN MACHINERY (1905)
THE POWER HOUSE (1907)
BOOKSELLER AND STATIONER (Est. 1884)
THE SANITARY ENGINEER (Est. 1907)
MARINE ENGINEERING OF CAN. (1910)
CANADIAN MOTOR, TRACTOR AND IMPLEMENT TRADE JOURNAL (Est. 1919)
CANADIAN FOUNDRYMAN (Est. 1909)
PRINTER AND PUBLISHER (Est. 1892)
THE FINANCIAL POST (Est. 1907)
MACLEAN'S MAGAZINE (Est. 1896)
FARMERS' MAGAZINE (Est. 1910)

This fact may interest you: namely, the MacLean organization is the largest concern of its kind in the British Empire. The output of its mechanical department every working day is the equivalent of a 150-page publication of the size and type of this copy of CANADIAN MACHINERY.

Our London Office: 88 Fleet Street, E.C.

Also at: NEW YORK, BOSTON, CHICAGO, MONTREAL, WINNIPEG

For over 20 years the MacLean Publishing Company has maintained a fully-staffed London Office, and has rendered British and Continental manufacturers, shippers, and traders an invaluable service in many directions.

Specimen copies of the MacLean Publications will be cheerfully forwarded to all asking for them. Address us at London or Toronto.

The Canadian Cartridge Co., Limited

HAMILTON ∴ ∴ CANADA

Used and New Machinery

Partial Selection From Our Big Stock:

PUMPS

One used 2" Downie Model A centrifugal pump.

Two size 5 Gould's centrifugal pump.

One size 2 Gould's direct motor driver centrifugal pump.

Two new Hydraulic Machinery Co. 4½" x 14" vertical hyd. pump.

One 6 x 4 x 6 Epping-Carpenter Duplex Steam Pump.

AIR COMPRESSORS

One 6 x 6 Nagle vertical air compressor.

One Canadian Ingersoll-Rand type R.P. 2, 29 x 12 x 16; 920 c.f.m. at 100 lbs. All in fine condition.

One used Jenckes Machine Co. class C. B. Air Compressor, size 10 x 10; capacity 190 c.f.m. Complete with unloading device.

One used Ingersoll-Rand class EI-1 Air Compressor, size 10 x 12; capacity 233 c.f.m. Complete with unloader. Practically new.

Two used Ingersoll-Rand 10 x 12 class E L-1 Air Compressor; capacity 275 to 290 c.f.m. at 100 lbs.; 220 r.p.m. Complete with air receivers. All in fine condition.

One Canadian Ingersoll-Rand class P L B-2. Size 20 x 20 x 16; speed 225 r.p.m.; 1508 c.f.m.; 300 H.P. motor at 600 r.p.m. Motor pulley 31½".

ENGINE LATHES

Two used 26 x 10 C.M.C. quick change gear, 3 step cone, double backed gear.

Three 24 x 12 Whitcomb Blaisdell, practically new, quick change engine lathe. Four step cone, double backed gear, 4" belt.

One 22 x 10 Milwaukee engine lathe, three step cone, double back geared.

One 20 x 8' 6" Petrie heavy duty plain turning lathe, equal to new.

Three 20 x 8 C.M.C. standard engine lathe, three step cone, double back geared, in good condition, each lathe fitted with four jaw independent 14" chuck.

One new 18 x 8 Stevens standard engine lathe.

One used 18 x 8 Stevens standard engine lathe.

One used 18 x 8 Greaves-Klausman standard double back geared engine lathe.

One used 18 x 8 Mueller quick change gear engine lathe.

One used 18 x 8 Cincinnati quick change gear, three step cone, back geared engine lathe.

Two used 17 x 8 Sydney, very heavy duty, standard double back gear, in good shape and very heavy pattern.

One used 18 x 8 Milwaukee standard single back geared, having 12" independent chuck, in good condition.

One used 18 x 8 Milwaukee standard single back geared having 12" independent chuck, and with taper attachment.

One used Hamilton 16 x 8 standard single back geared, type B, with 10" independent chuck fitted, in fine condition.

One old 16 x 8 McGregor-Gourlay engine lathe, good for someone wanting very cheap lathe.

One used 16 x 7 Hendey lathe, mounted in oil pan and with bracket for taper attachment, complete with regular equipment.

One 14 x 8 ft. Hendey used engine lathe; good condition.

TURRET LATHES

One used No. 6 Foster, geared friction head turret screw machine.

One used 24" Gisholt turret lathe, with taper attachment. Hole through spindle 4¼ inches, three step cone for 4 inch belt, chuck 24" diameter. Four square turret tool post.

Two 1⅝ x 7 New Britain six spindle automatic screw machines.

Ten No. 33 New Britain multiple spindle automatic chucking machines, equal to new.

DRILLING MACHINE

One used 4' Bertram plain radial drilling machine, thoroughly overhauled and refitted.

One new 26" Aurora heavy type upright drilling machine.

Three new 20" C.M.C. upright drills.

Twenty used Henry and Wright No. A, class "B" ball-bearing sensitive drills. 15" swing.

50 Avey No. ½ single spindle ball bearing bench drills.

50 Avey No. ½ double spindle ball bearing bench drills.

Four used Leland and Gifford heavy duty ball bearing 14" two spindle sensitive drilling machines.

MILLING MACHINES

One new No. 3 Ford-Smith plain miller, 34 x 10 x 20.

One new No. 2 Ford-Smith full universal miller, 25 x 8 x 17.

One new No. 2 Ford-Smith plain miller, 24 x 7½ x 19.

One new No. 1 Dow plain miller, 24 x 7 x 18, all complete.

One used No. 1½ Rockford plain miller, having vertical milling attachment, also slotting attachment and universal dividing head in splendid condition.

Five used No. 7 Becker Lincoln millers, with cabinet leg and oil pump, especially suited for key way cutting and manufacturing.

Six used No. 12 Pratt and Whitney Lincoln millers.

One used No. 1B Milwaukee universal miller, good condition.

GRINDING MACHINES

One used No. 2 Reid Bros. automatic surface grinder, complete with magnetic chuck, all in fine condition.

One used No. 3 Brown and Sharpe 12 x 40, universal grinder.

One used No. 70 Heald internal grinder with type No. 7, style No. 1 head.

One used No. 1 Diamond automatic surface grinder. Range 24 x 12 x 9, with magnetic chuck.

One used No. 3 Wilmarth and Morman automatic surface grinder, with No. SF 8 x 20 D. and W. Fuse Co. magnetic chuck.

One No. 2 Brown and Sharpe used surface grinder, good condition.

One Landis used 10 x 30 plain grinder, good condition.

POWER PRESSES

Six used No. 18 Bliss fly wheel presses.

One used No. 73½ Bliss straight sided trimming press, fly wheel type, with side cutting off attachment.

One used 90-lb. Waterbury Farrell drop hammer, complete with power lifter counter shaft.

One used 120-lb. Waterbury Farrell drop hammer complete with power lifter counter shaft.

One No. 4-A Styles adjustable bed power press, 4" stroke.

Two No. 8½ Zeh and Hahnemann patent percussion presses.

Two No. 10 Zeh and Hahnemann patent percussion presses.

Two No. 12 Zeh and Hahnemann patent percussion presses.

MISCELLANEOUS

Three 1" National triple head bolt cutters, capacity for threading ¼ to 1 inch diameter.

One 1½" National triple head bolt cutter, capacity up to 1½".

One Acme six spindle nut tapper, capacity ⅜ to 1 inch.

One 1¼ inch National semi-automatic nut burring machine, for burring all sizes from ⅝ to 1¼ inch.

One No. 1 Lapointe Broaching Machine, used, good condition.

One No. 3 Lapointe Broaching Machine, used, good condition.

FURNACES

Six Monarch No. 275 tilting crucible furnaces, in fine shape.

Do you want help or have you something to sell, if so use the classified column in this paper.

Do Your Bit!

BUY W-S WAR-SAVINGS STAMPS

DO not think patriotic work is a thing of the past. The great need to-day is to repatriate the returned soldier, and to promote Prosperity so as to solve the problem of the War Burden. The Dominion of Canada requires your help.

You can be a vital factor in the Government's plan to sell War-Savings Stamps by getting your customers to buy Thrift Stamps.

If they buy the Thrift Stamps from you, they will soon be War-Savers, helping themselves and the country in the great work of Reconstruction.

Put up your Thrift signs, get your stock of stamps, and push the sale among your customers.

Every Bank and Money-Order Post Office carries Thrift Stamps.

Sell Thrift Stamps

The City of Sarnia

The Gateway to the Upper Lakes

Mr. Manufacturer, study the location of Sarnia on the map and ask yourself this question:

COULD SARNIA BE BETTER LOCATED?

With our frontyard an immense waterway, in fact, the world's most industrious waterway, and with transportation by rail so accessible, there is nothing in location whereby Sarnia could be bettered.

In the past, Sarnia has been built substantially with none of the semblance of a boom. In the future, Sarnia will be built as substantially with the boom which is only possible by its citizens' investment of faith in its bright future. These are days of reconstruction; we stand at the portals of a new day and see just ahead of us important strides in progress.

A summary of the advantages Sarnia offers to manufacturers seeking sites for new plants:

Sarnia is located at the gateway of the West. It is the terminus of the Grand Trunk Railway, with the world-famous St. Clair Tunnel, and the headquarters of the Northern Navigation Co. and P.M. Rly. Best shipping facilities and abundance of electric power at reasonable rates.

The City Beautiful

Living conditions are ideal; no strikes or labor disturbances of any kind.

It has a delightful residential section; miles of paved streets, beautifully shaded; fine homes; clean streets; summer homes on Lake Huron; free bathing beaches. Two boats daily to Detroit. Main line double track Chicago to Montreal.

Investigate Sarnia Now. For full particulars re manufacturing sites, write

MORGAN CHASE,
Secretary, Chamber of Commerce.

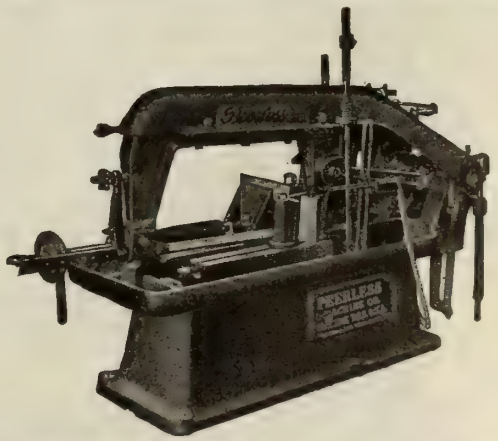
Peerless HIGH SPEED

Has Proven Its Efficiency Where Others Have Failed



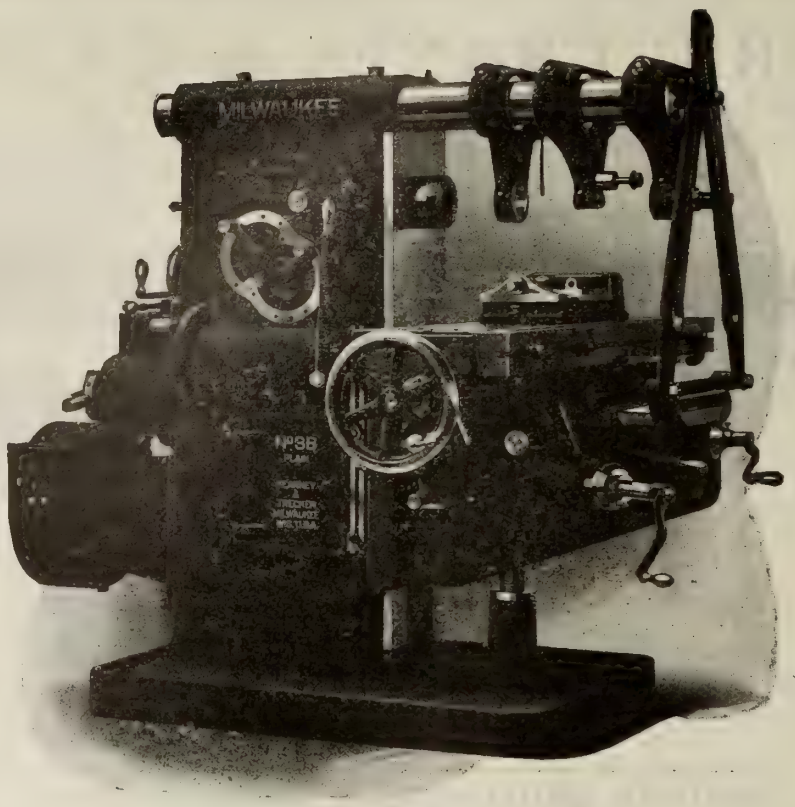
DON'T turn down the "Peerless" because you have tried out other hack saws which did not answer your requirements.

Many concerns who were persuaded only with the greatest difficulty to try their first "Peerless," because they "just knew it would turn out like the others," are to-day among the largest and best-satisfied users of our High-Speed Saws.

The "Peerless" is different—and better. It does 50 to 100 per cent. more work, cuts with thinner saws and requires a minimum of attendance, saving time, labor, material, blades and floor space. What is your work? We can tell whether the "Peerless" will do it, and back our judgment with a 30-day trial. If it doesn't make good we pay freight both ways. Well?

PEERLESS MACHINE CO.

1607 RACINE STREET RACINE, WISCONSIN



MILWAUKEE MILLING MACHINES

Double Overarm maintains alignment.

It is impossible for the operator to place the arbor supports on the arbor and double overarm in any other way than in line. Arbor cannot be pounded out of line when using large, coarse pitch cutters on rough, heavy work.

Other Distinctive Milwaukee Features:

Solid top knee—hardened steel gearing and shafts in the column and feed box—automatic flooded lubrication—one and one-half gallons of oil per minute pouring over all gears and bearings in the column and feed box, insuring lubrication at all times—flanged spindle with hardened steel collar for driving arbors—constant speed drive, reverse being self-contained.

Send for our No. 21 Catalogue. Illustrating and describing Milwaukee Milling Machines and accessories in detail

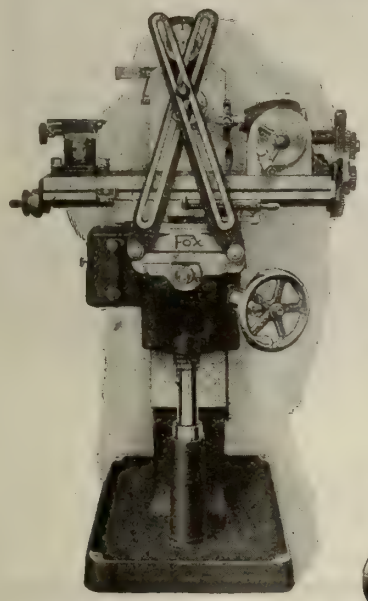
KEARNEY & TRECKER CO.
MILWAUKEE, WIS. U.S.A.

TRADE FOX MARK
REGISTERED

MILLING MACHINES

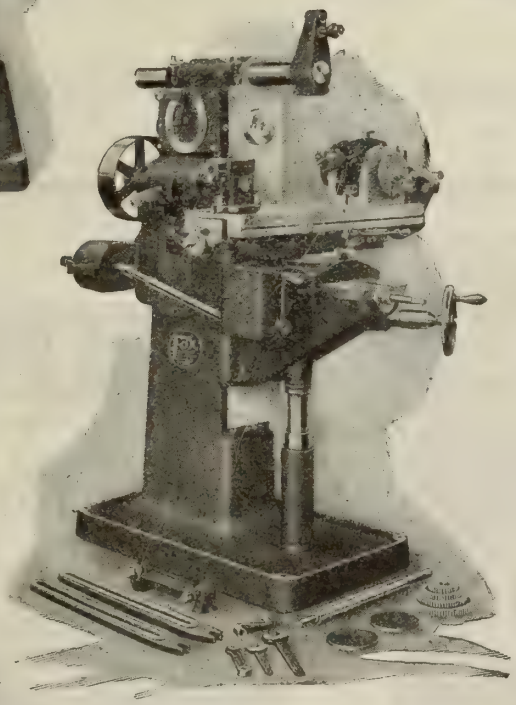
FOR

Rapid Production of Motor Parts



The **demand** for increased production **requires tools** of **great strength** and **durability;** the Fox 2-A Universal Milling Machine illustrated has met this demand, and is being used wherever extreme accuracy and quantity production are required.

The machine has a universal table, spiral cutting attachment, 10″ Dividing Head with 6″ Universal Chuck, making it a machine **especially adapted for Tool Room Work.**



The **United States Government** used this machine in its various **repair shops** for **Aeroplane Motors.**

You should be using this tool to help the production of parts necessary for reconstruction.

Specifications—No. 2-A Miller.

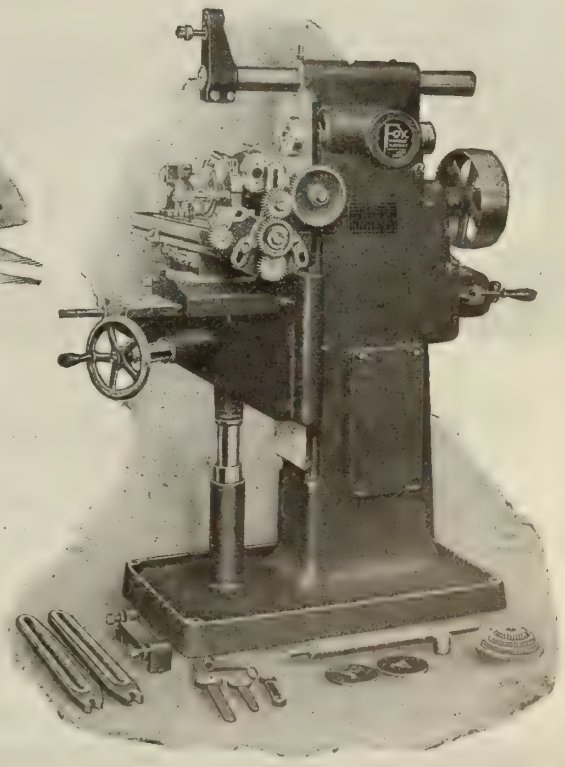
Spindle speeds 12
From 21 to 423 r.p.m.

Table feeds 6
From .317″ to 2.79″ per min.

Table .....8½ x 27″
Long. feed (power) 26″.
Vertical feed (hand) 13″.
Trans. feed (hand) 8½″.

Drive...Single pulley 10 x 3″ running 250 r.p.m.

Gears — Hardened steel.
Weight .....1,500 lbs.



We build this same machine with a plain table, omitting the spiral cutting attachment and Dividing Head.

Our No. 1 type machine has a four-step cone drive, and while being a lighter machine is a "bear" for work. This was proven by **the hundreds** of **them in the largest munitions plants.**

We also build the Fox Multiple Spindle Drilling Machines.

FOX MACHINE COMPANY

1047 W. Ganson St., Jackson, Michigan, U.S.A.

Wherever Pipe is Cut or Threaded Economically

The probability is two to one that it's a

Williams Pipe Machine

that's on the job.

For in approximately two-thirds of all the larger plants in this country Williams' Pipe Machines are used.

It was the Williams Pipe Machine that brought highest honors home from the Panama Exposition.

The Machine illustrated has a capacity of 21½″ to 12″. Also nine other sizes to meet your requirements.

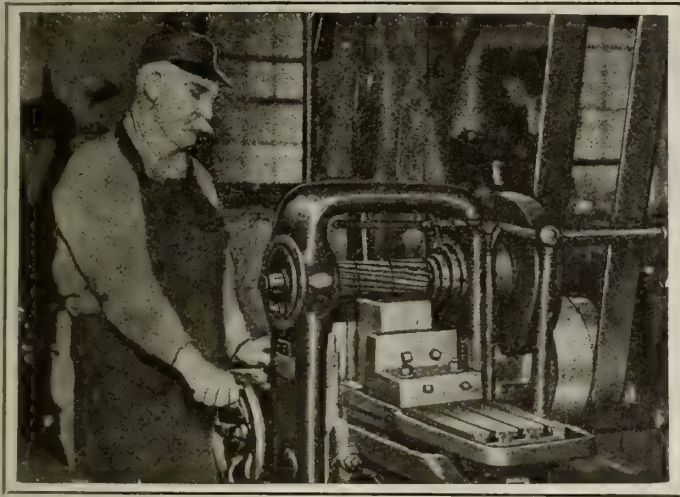
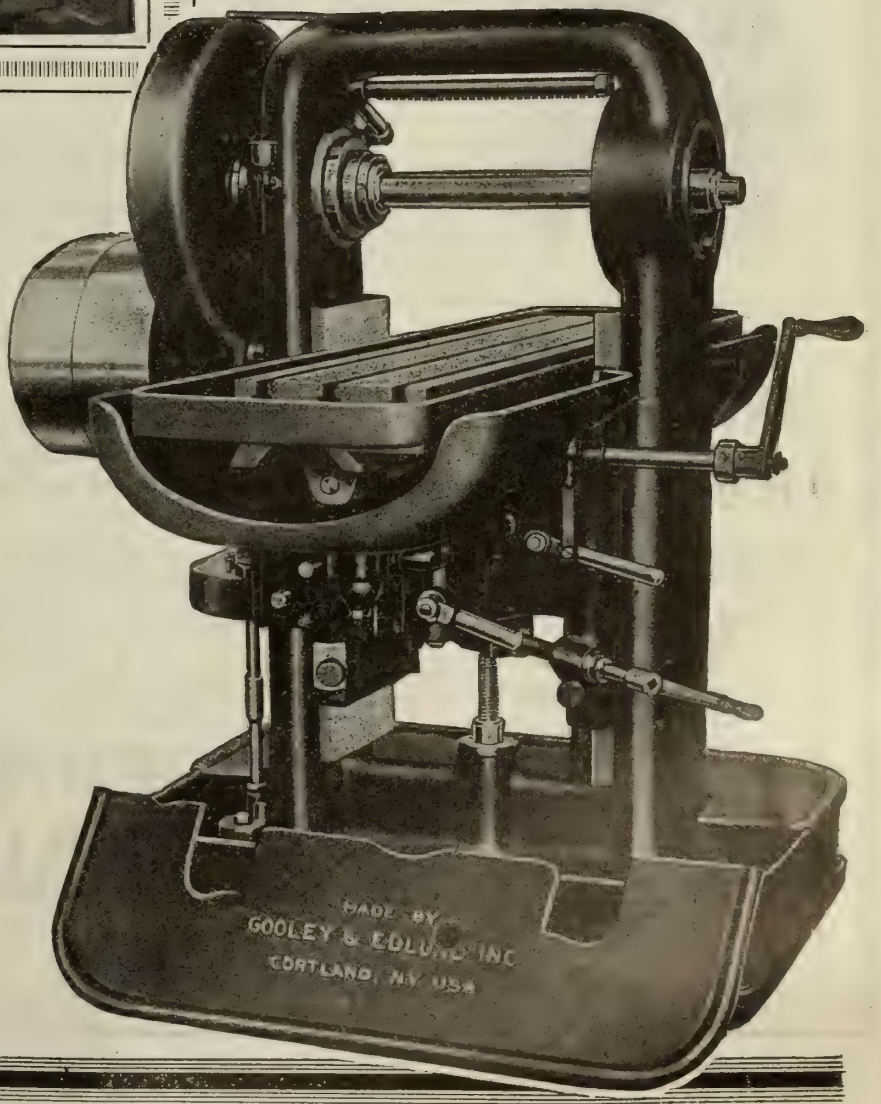
BRIGGS MILLER

Keeps Five Die Sinkers Going





HERE you see the Briggs Miller Squaring Die Blocks, and it is working so fast it keeps five die sinkers going.

Some are new, squared from the rough; some are old, annealed, cut down and made over; some are oblong, some square, in sizes up to 9 inches. This Briggs Miller has been squaring blocks for four years; has never given any trouble. When cutters get dull the operator has another gang ready to go on with the work. Unusual rigidity accounts for Briggs' higher efficiency.

Don't you think you could use this tool to advantage in your shop? Write for the details.

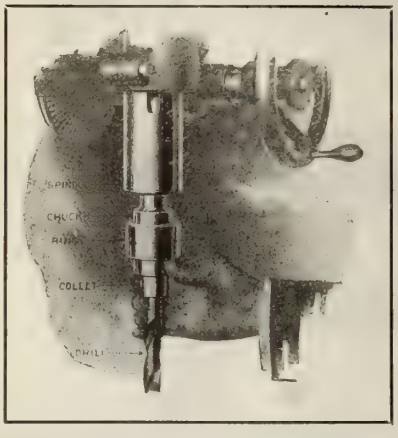
MODERN TOOLS
MAKE BUSINESS HUM



The Modern Line supplies indispensable aid in business progress. Modern Tools are precision tools of the finest quality, noted for accuracy, dependability, volume of output and durability. We make:

—Modern Plain Grinders
10 sizes—8″ x 18″ to 16″ x 60″.

—Modern Internal Grinders
One model with fixtures in 3 sizes.

—Modern Universal Grinders
Normal range 13″ to 40″.

—Modern Chaser Grinders
For any chasers with parallel sides and general tool room work.

—Modern Self-Opening Die Heads
18 sizes—for threads up to 7 inches.

—Modern "Magic" Chucks
For quick change of tools on live spindle machine.

—Modern Collapsible Taps
3 sizes—Will tap holes ¾″ to 3″.

—Modern Tapping Attachments
For driving tools "through" or "to bottom."

All are tools of widespread use in the States—all have enviable records for reducing costs and speeding up production.

Send for technical bulletin of any which may interest you.

Send us your specifications and blue prints for data on your particular kind of work.

INDUSTRIAL REVIVAL DEPENDS ON YOU

Start your own ball a-rolling.

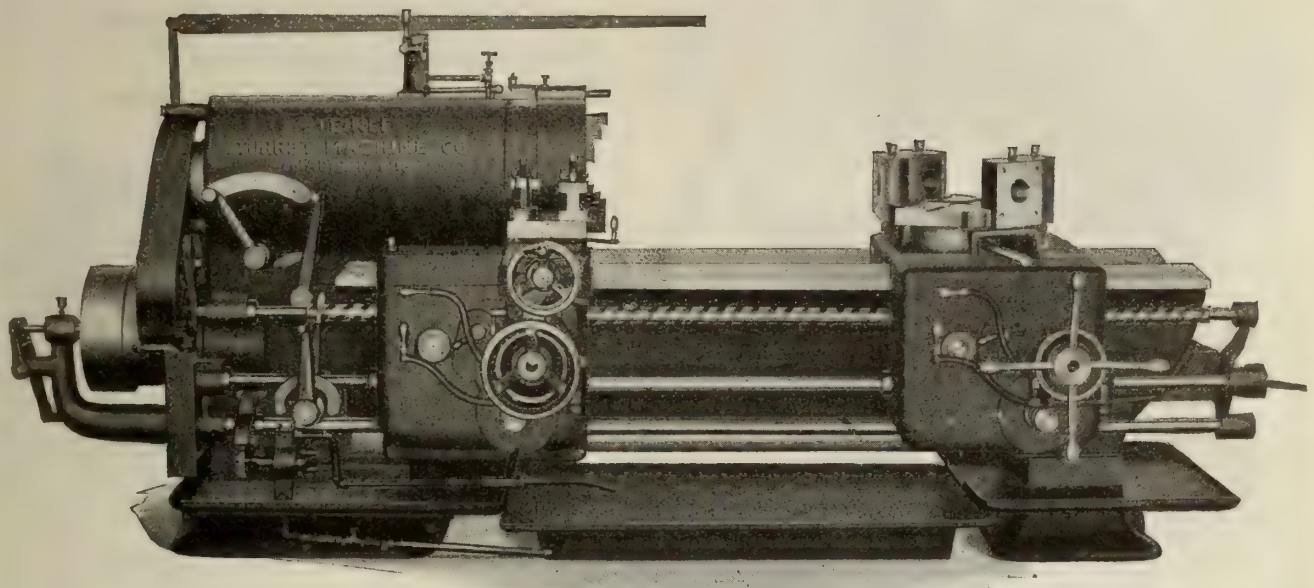
STEINLE



Another reason why the Steinle 24″ Full Swing Side Carriage Turret Lathe is ahead of all others in the economical and accurate production of many classes of work.

The One Piece Box Construction Design of Bed and Headstock Housing

The headstock is entirely enclosed on front, top and bottom sides, and also on the back with the exception of an opening left for assembling purposes and for which a suitable cover is provided. This design furnishes substantial support for the main spindle bearings and also for all driving shafts.

The bed is enclosed on all four sides and designed to withstand torsional strains and to properly support the side carriage and turret in alignment with spindle when carrying heavy tool loads.

This bed and headstock housing by reason of the amount and proper distribution of metal absorbs all vibration due to heavy cuts, and shock or jar incidental to heavy intermittent or uneven cuts.

There are more good reasons why the Steinle 24-inch Full Swing Side Carriage Turret Lathe is ahead of all others in the economical and accurate production of many classes of work. We will give these reasons in future advertisements in this journal. Watch for them. They will be interesting to you.

STEINLE TURRET MACHINE CO.

War Record Not Made Public

The "Whitney" Special Quality "Type M" Chains

made a great showing during the war years 1916-7 and 1918.

Our tests and demonstrations were made on prominent 8-cylinder motors in service on a large number of cars in the State of Connecticut.

During this long period not a single "Whitney" Chain or Sprocket had to be replaced and the condition of every Drive has been pronounced remarkable.

One Drive recently examined had given over 35,000 miles' service and both Chains and Sprockets were in such perfect condition that they appeared good for more than double that record (Sprockets having no adjustment).

The links of this SPECIAL CHAIN have finished faces and reamed holes, and the smooth faces do not damage the Sprocket teeth.

Our war contracts were such that we did not announce this SPECIAL CHAIN until after the conflict was over.

Planers

Give a Tribloc severe service

—use it every day
—work it to capacity
—let anybody "run" it
—operate it indoors or out

It never falters, never fails. It's built for service and "delivers."

Gears, chains, hooks and all working parts are made of steel. The **Loop Hand Chain Guide** prevents "gagging" of the hand chain, injury to the block and overriding of the flange when working at high speed.

For a safe, durable, dependable hoist—a **Tribloc,** with capacities of ½ to 40 tons. Guaranteed (in writing) for five years.

UNION

POSITIVE DRIVE DRILL CHUCKS

The Union Drill Chuck is made in seven sizes (0 to 2 inches) with PATENT TRANSVERSE SLOT—so that drills with tenons can be inserted (see illustration). The shank of drill should be squared on two sides to enter the TRANSVERSE SLOT, giving a positive rotation to the drill independently of the jaws, permitting the jaws to centre and align the drill accurately. The drill is held absolutely true and will not slip under the hardest strain. This type of chuck will be found to give the best results on all classes of work from HIGH SPEED drilling to the hard BLACKSMITH and GENERAL REPAIR work.

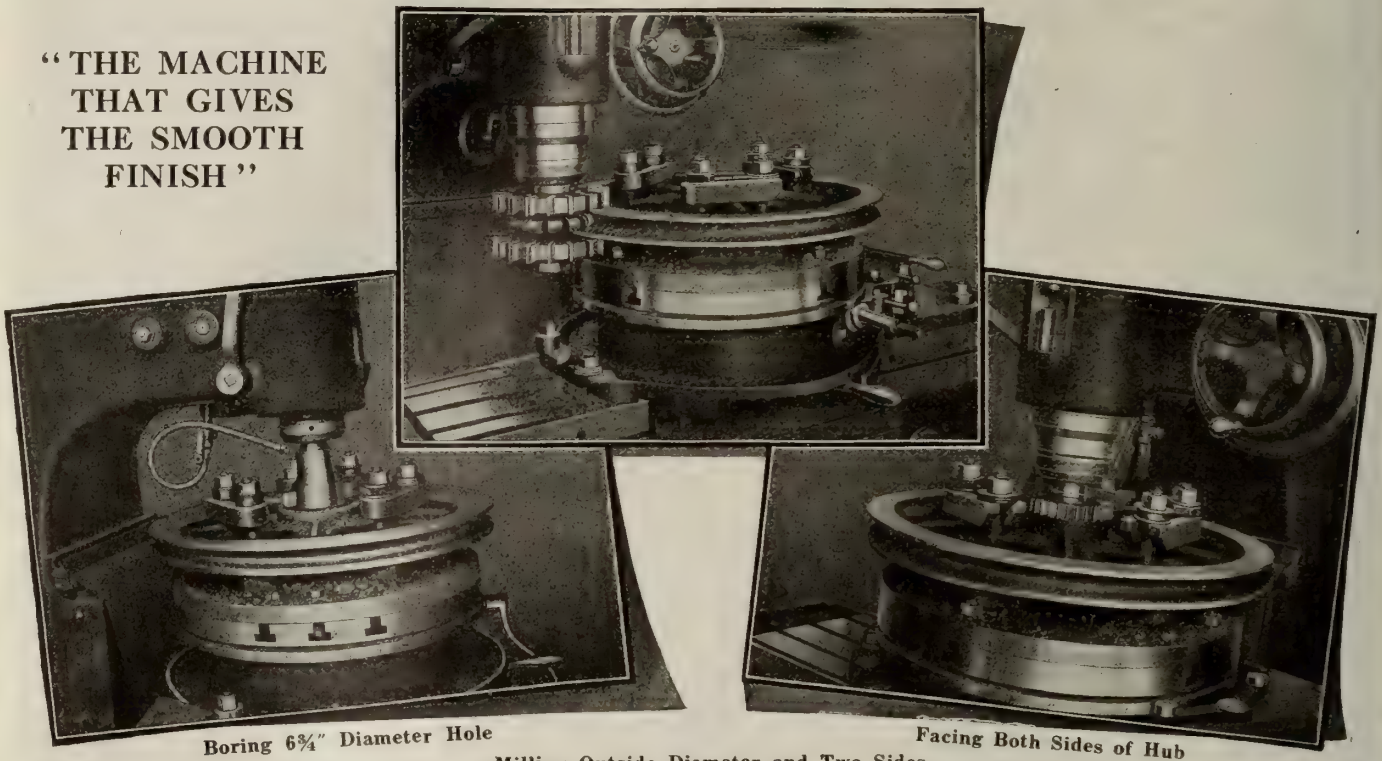
DOUBLE PRODUCTION

ON THE SAME JOB BY THE SAME WORKMEN

"THE MACHINE THAT GIVES THE SMOOTH FINISH"



Boring 6¾" Diameter Hole

Milling Outside Diameter and Two Sides

Facing Both Sides of Hub

A SIMPLE PROOF OF MACHINE SUPERIORITY

The photographs shown above were taken in the plant of the Mead-Morrison Company at East Boston, Mass. They show real every-day operations—not just posed for photographic purposes—and operations on which the manufacturers have doubled their production by using Becker Belt Driven Millers.

Prior to the installation of Becker Vertical Millers, the best production attained was on a boring mill, 3 hours being consumed. Becker Belt Driven Millers have cut this in half—1½ hours being the time consumed now on the same operation, and the finish is smoother, more accurate and better.

A similar saving may be possible in your plant—Investigate to-day—Now!

Photographic Copying
The PHOTOSTAT
(Trade Mark Registered)

"Orders are now delivered three or four days earlier to our customers by making photographic copies of sketches and drawings which are the same in every detail instead of having our draftsmen reproduce the original.

"Practically all orders were previously held up three or four days by our drafting department while copies of the intricate drawings of ordered tools were being made. Now with the Photostat, only 15 or 20 minutes are required to make the three copies, exact duplicates of the original, which the factory needs to turn out the order. By eliminating this needless delay we are able to provide better service for our customers, and attract new prospects because of prompt deliveries."

This cut shows a PHOTOSTAT on which a large drawing has just been copied in less than a minute.

Never Makes a Mistake

It is simple, practical, easy to handle. Requires no expert knowledge. The machine is loaded with a roll of sensitized paper especially manufactured for the purpose.

The original subject is photographed directly upon this paper producing a facsimile copy which is immediately cut off, developed and fixed right in the PHOTOSTAT itself.

The focusing, exposing and developing are all controlled by simple mechanical devices and no glass plate, film or other intermediate negative has to be made.

After fixing, the copy is removed to a tank of running water and rapidly washed free from chemicals. It is then dried and is ready for use. As many copies as desired may be run off in this manner.

By a simple adjustment of the mechanical focusing device the copy may be made at actual size, reduced, or enlarged, within the size limitations of the machine.

Error in copy is impossible because every copy is an absolute facsimile. The operations are all simple, such as a boy or girl can do.

THREAD MILLERS
Manufactured under the Holden & Morgan Patents

HOW WE DO IT---

The line drawing shows the Foster method of performing the first operation on a ring bevel gear. Incidentally it also illustrates the big value of the rear cross slide tool holder in reducing the production cost.

The time on this production is very short. Are you interested? Write us and we will give you actual production figures; also show you how we do the second operation.

Is our 2-B Catalogue in your files?

FOSTER MACHINE COMPANY, ELKHART, Ind., U.S.A.

Don't Read This Ad—

If You Want To Throw Away Money

on transmission troubles. As you well know, there's no easier way to spend money than on power losses, hot boxes, lubrication, etc. Thousands are spent yearly in fighting these evils. But, if you are reading this ad, you are tired of paying for these troubles. Good! Here's the panacea: **Chapman Type Ball Bearings** are durable almost to the point of permanency; save an average of 20 per cent. on power; eliminate 75 per cent. of your friction losses, and 95 per cent. of lubrication and attention. All your power is delivered to your machines. And they fit the frame you now have in your shop.

You have read this ad. Then find out about Chapman Bearings for your shafting hangers, pillow blocks, loose pulleys, friction clutches or wherever you employ bearings.

The "Why" of Steel Shelving

DENNISTEEL Shelving takes proper care of stock, preventing waste and careless handling, saving time in finding the thing required. It provides 25% more storage capacity than wooden shelves, saving valuable floor space. In stock-taking, everything is simple and quick—the stock is rightly kept. **DENNISTEEL** Shelving is adjustable to requirements, will carry heavy loads, is vermin and rodent proof; will not rot, crack or split; is **FIREPROOF**, reasonable in cost and lasts a lifetime. This, we believe, will appeal to you as a money-saving proposition and economy. Write for folders, please.

DENNISTEEL
Made in Canada

The CANADIAN Disc Sander Is 90% Dustless

Think what a godsend that is to the pattern shop! Hundreds of prominent concerns are profiting immensely by using these sanders.

Two types of Canadian sanders are built—the Disc Sander, and the Oscillating Spindle Sander. Both machines are equipped with New Departure ball bearings and General Electric motor. The table in each case can be tilted by a hand adjustment, 45 degrees down or 15 degrees up. Power is obtained by plugging into a lamp socket.

Canadian Sanders are extraordinarily well built and are guaranteed against all defects.

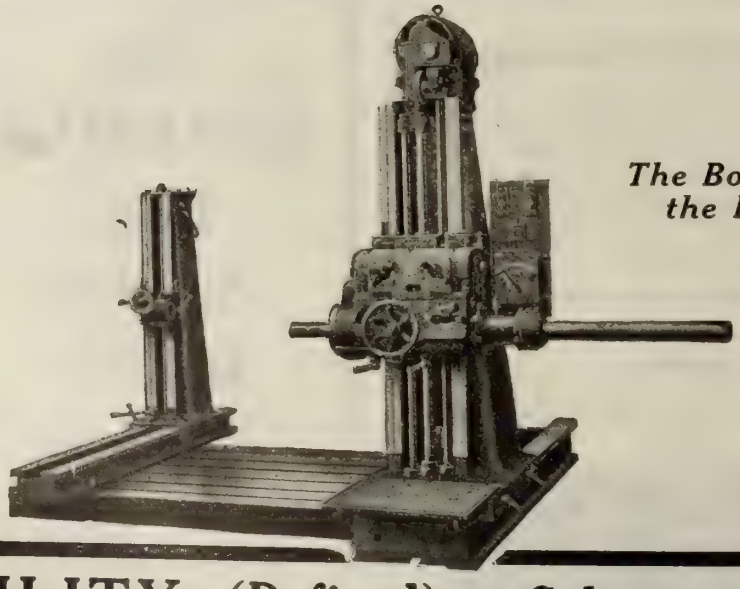
LANDIS



The Boring Machine with the Powerful Spindle

Boring, Milling and Drilling Machine

DURABILITY (Defined)—Columns sidebraced

in two directions and well proportioned for rigidity. Floor plate and runways of solid web construction and very stffly ribbed, Bearings of high grade bronze, Gears and Shafts of chrome nickel steel and specially heat-treated—these are the features which contribute to the unequalled DURABILITY of this machine.

A machine possessing such DURABILITY and capable of as many as seven different operations on large work with only one chucking is the machine for intensive production.

Our Boring Machine Catalog gives complete data.

LANDIS TOOL COMPANY, Waynesboro, Pennsylvania, U. S. A.

BEVEL
BEVELS

Skilled Artisans Prefer Standard Grade Tools

The skilled mechanic must have sharp files, otherwise he gets no satisfaction out of his work.

As soon as his file becomes dull, tell him to turn it in and get a new one. The result will be better work and greater satisfaction to all concerned.

And it pays. New files cost little, labour costs much.

Good steel, accurate cutting and proper hardening insure long life to "Famous Five" files.

Specify them when ordering.

How Much Do You Lose Each Year Through Slipping Belts?

Many factories and mills are losing hundreds and even thousands of dollars a year through power losses and coal waste in the operation of their pulleys. This waste is due to belt slip and air fanning, which exists to an extent little recognized by the management.

AMERICAN STEEL SPLIT pulleys solve the problem of belt slip. They are guaranteed to reduce it to a minimum. They lengthen the life of the belt.

The face of the "American" Pulley has a high co-efficient of friction and grips the belt. The sharp edges of the arms are constructed to cut the air and reduce air fanning to the lowest possible degree. The air groove in the face of the pulley also helps to minimize belt slip.

American Steel Split Pulleys are manufactured to give maximum strength with minimum weight check transmission losses and transmit power with great efficiency. They are guaranteed for double belt service and recommended for rim speeds up to 6,000 feet per minute.

National Distribution through supply houses from parent stock in the larger cities.

Our book, "Getting Maximum Pulley Efficiency," will tell you how to effect transmission savings. Sent free on request.

The American Pulley Company

PHILADELPHIA, PA.

Canadian Machinery BUYERS DIRECTORY

If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

The Value of the Business Press to Business Men

"Business men do not realize the value which trade journals and technical magazines may have for them in increasing the efficiency of their factories and in giving them a broad and comprehensive view of their business.

"Our foreign competitors read almost every article published upon their business with great care and thoroughness. Many of them have duplicate copies of their favorite trade paper sent to their homes so that they may read them away from the business without being disturbed. Many foreign manufacturers contribute articles to these journals on phases of the business with which they are most familiar. Such articles are bound to be helpful and have a constructive effect.

"Our trade journals and technical papers are the best in the world, and they should be supported and encouraged by our business men.

"Copies should be placed where employees can see them and they should be urged to read and study them.

"These papers are preaching the gospel of sound business on practical lines and are helpful not only to business but to the country as a whole.

"If the suggestions made by them in the past had been followed by our business men it would not be necessary at this time to point out some of the fundamental weaknesses in American business."

—Edward N. Hurley, formerly Chairman of the Federal Trade Commission, in "The Awakening of Business."

The following is list of the MacLean publications. Every publication is a leader in its field. Write us for any information you may desire with regard to the field covered, advertising rates, etc.

Adjustable External Limit Gage in Use in Turning Work

T-P Tool Room Specialties
Limit Gages of Unlimited Utility

External Limit Gage Style 31

External Limit Gages

Taft-Peirce External Limit Gages are made from tool steel drop forgings and are so designed as to be extremely rigid and yet have large, easy measuring surfaces. They are carried in sizes that are multiples of 1/16 in. up to 3 in.—adjustable gages to 7 in.—while other sizes are finished to customers' specifications.

Limit Plug Gage

Limit Plug Gages

Taft-Peirce Limit Plug Gages can be purchased from stock in all usual sizes and limits. The gage is made up of three units, a "Go" plug Style 11, a "Not Go" plug Style 12, and a handle Style 13, all of which are carried in stock sizes in multiples of 1/16 in. These plug members are so designed that they may be reversed on the same handle by simply removing the screw and turning the plug around. Larger and special sizes are made to order. Bulletin No. 104E describes the complete line of T-P gages and other tool room accessories. Ask for it.

SAVES SPACE POWER TIME

"STAR" LATHE

The simplicity of construction and ability to stand long, hard usage makes the "STAR" invaluable for hard work.

The remarkable success of the "Star" lathe for repair work and light manufacturing is due to the fact that we have been concentrating on small lathe manufacture for 36 years—building a small lathe so accurate and rigid that it can replace heavier and costly equipment.

The "Star" lathe will save you floor space—first cost—power. In addition to its operating simplicity means increased production. Sizes—9″, 11″, 12″, 13″ swing.

PATTERNS Hand and Machine

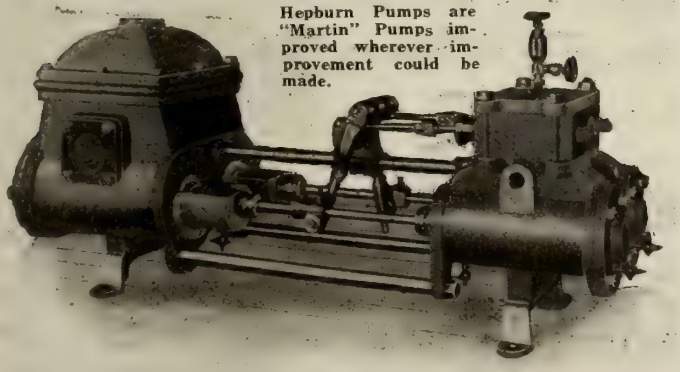
Hepburn Pumping Machinery

Our line embraces standard duplex pumps for boiler feeding and for fire and general service; tank or low service duplex pumps; duplex hydraulic pumps for service in connection with hydraulic lifts and presses, accumulators and oil presses; pressure or mine pumps; horizontal power pumps and air and circulating pumps, etc.



Hepburn Pumps are "Martin" Pumps improved wherever improvement could be made.

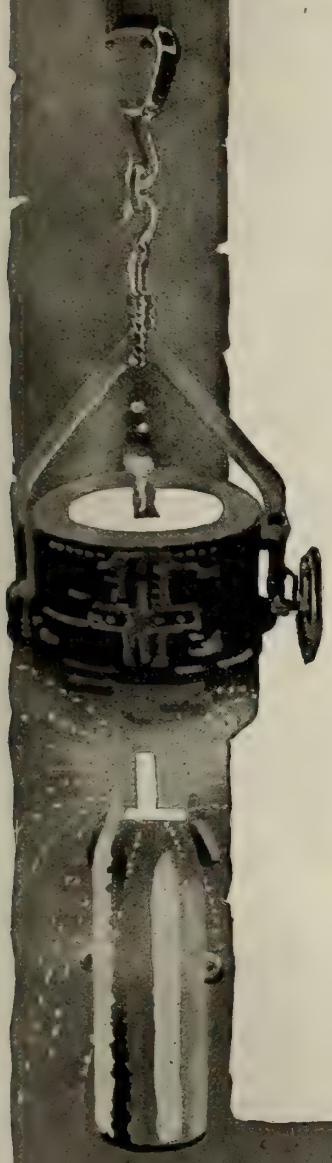
Nichrome Castings for Heat Treatment



Cast "Nichrome" and Ferrous Materials For Heat Treatment

The performance of cast iron, cast steel, structural steel and wrought iron in heat treatment has never been satisfactory. Ferrous castings contain blow holes, slag inclusions, sand and foreign material, all of which affect the time rate of heat penetration. The repeated heating and cooling of ferrous materials from room temperature to 1800° F. for several hours results even in a reducing atmosphere in the material becoming blistered, burned, cracked and covered with scale; thereby producing thin spots in the walls and ultimately holes are burnt through.

Under the influence of heat, Cast Nichrome DOES NOT CRACK, GROW, WARP or SCALE. Being heat resisting and durable, it minimizes and practically eliminates costly expenditures for repairs and maintenance. The life of carbonizing boxes and other heat treating containers is 25 to 48 times that of ferrous materials under the severest conditions.

Write for further particulars.

Manufactured under Henderson Patents.

The MIGHT of Simplicity

Newton, hit by a falling apple, evolved the law of gravitation.

Marconi, with a kite, a wire, a tube and a few patches of metal, created the wireless.

Edison, with a little film, turned the world's nights into days.

The Clipper Belt Lacer, fundamentally as simple as any of these, has given the world another lesson in the Might of Simplicity. It has revolutionized the speed by which industry's belting can be repaired.

In nearly a hundred thousand industrial plants Clipper hooks are implicitly relied upon to lace the belts upon which continuous production depends. In past strenuous days the Clipper has kept production at the maximum. It has saved untold losses in production hours. It has prevented the shop panics of other days, when it took from fifteen minutes to half an hour to make even an inferior joint.

The Clipper Belt Lacer
Laces a Belt in Three Minutes

—and laces it perfectly—makes a smooth, flexible joint, flush with the belt on both sides, one that pulls better and is safer. The Clipper goes to manufacturers on free trial. It is backed by a perpetual guarantee. The Clipper is the solver of belt lacing problems the world over.

Some mill supply dealer in every city sells the Clipper. European trade supplied through London office, No. 10 Norfolk Street.

POWER -- BENDERS

THREE NEW MODELS

"Wonder" Pipe Bending Machines (pat.)

Electrically operated to bend from 1/8" to 20". Send for printed matter. We also manufacture TEN other sizes, hand operated benders.

American Pipe Bending Machine Company

52 Pearl Street — Boston, Mass., U.S.A.

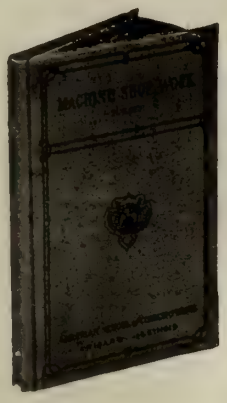
YOU'LL FIND WHAT YOU WANT

In the Classified Advertising Section of Canadian Machinery. Watch it each week for all kinds of new and used machinery.

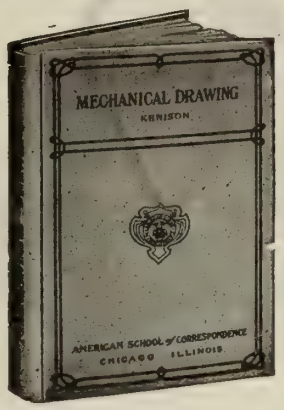
YOU MAY WANT WHAT YOU FIND

Mechanical Engineering Books

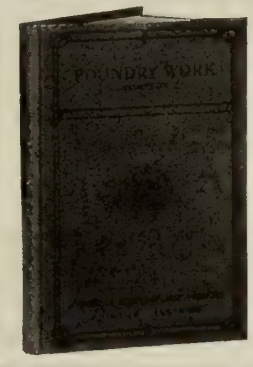
If you are desirous of improving yourself in your trade and so putting yourself in the position of making more money, these Mechanical Engineering Books will be found helpful.



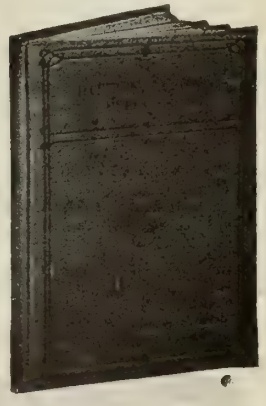
MACHINE-SHOP WORK. By **Frederick W. Turner,** Instructor in Machine-Shop Work, Mechanics Arts High School, Boston. 208 pp., 241 illus. Cloth binding. The use of various hand tools is explained, followed by a comprehensive discussion of the lathe and lathe tools, with the methods of screw cutting, taper and eccentric turning, etc. The way to figure compound gears for screw cutting; drilling; boring; planers; shapers; slotters; milling machines and cutters; how to cut spirals, gears, cams, etc.; grinding; the operation of automatic machines. Price $2.00



MECHANICAL DRAWING. By **Ervin Kenison, S.B.,** Assistant Professor of Mechanical Drawing, Massachusetts Institute of Technology. 176 pp., 120 illus. Cloth binding. Gives a course of practical instruction in the art of Mechanical Drawing, based on methods that have stood the test of years of experience. Includes orthographic, isometric and oblique projections, shade lines, intersections and developments, lettering, etc., with abundant exercises and plates. Price $1.25

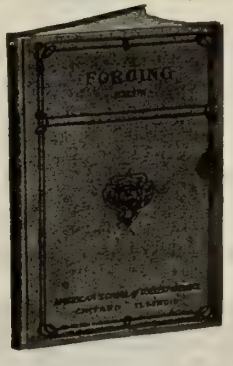


FOUNDRY WORK. Revised by **Burton L. Gray,** instructor in Foundry Practice, Worcester Polytechnic Institute. 224 pp., 191 illus. Cloth binding. A practical handbook on standard foundry practice, including hand and machine molding, cast iron, malleable iron, steel and brass casting, foundry management, etc. Includes use of various types of molding machines. Price, $1.25



PATTERN MAKING. By **James Ritchey,** Instructor in Wood Working, Armour Institute of Technology. 160 pp., 250 illus. Cloth binding. Shows the reader how to take the blueprint and from it make the pattern for any kind of casting under any condition. The allowances for shrinkage, draft, and finish are explained. Simple and built-up patterns of all kinds are clearly treated. Various special cases are taken up, such as pulleys, cranks, pipe connections, valves, etc. Price.....$1.75

MACHINE DESIGN. By **Charles L. Griffin, S.B.,** Assistant Engineer, the Solvay-Process Co., American Society of Mechanical Engineers. 208 pp., 82 designs. Cloth binding. Explains in detail how to make the entire design of all kinds of machinery, how to lay out gears, etc., with complete specimen designs of numerous machines. Price ... $1.75



FORGING. By **John Lord Bacon,** Eng. and Supt. of Construction, with **R. P. Shields** & Son, San Diego, Cal., American Society Mechanical Engineers. Author of "Forge Practice." 128 pp., 180 illus. Cloth binding. A working handbook of practical instruction in hammering, working, forming, and tempering of wrought iron, machine steel, and tool steel, including the important modern development of electric welding. Price $1.25

TOOL MAKING. By **Edward R. Markham,** Consulting Mechanical Engineer, formerly Superintendent of the Waltham Watch Tool Co., American Society of Mechanical Engineers. Author of "The American Steel Worker." 224 pp., 325 illus. Cloth binding. Takes up the methods of treating tool steels—annealing, tempering, spring tempering, hardening, case-hardening, etc.; how to make drills and reamers of all kinds; the making of arbors and mandrels, taps, hobs, reamer and tap-holders, jigs, gauges, dies and die-holders of all kinds, counterbores, facing tools, milling cutters, hollow mills, and forming tools. Gives all necessary information for tool making in all its branches. Price $1.75

Sent postpaid on receipt of price. We can also furnish you with other standard works on Engineering in all its branches, including books for Civil Engineers, Contractors, Electricians, Foundrymen, Steam Engineers, Mechanical Engineers, Municipal Engineers, Railroad Engineers, Sanitary Engineers, Gas Engineers, Hydraulic Engineers, Technical Men.

The Secret of the Strikes

Most Canadians are asking "What is the cause of the 'Great Unrest' "? Is it the fault of labor—or of capital?—or is it the result of German propaganda? Do you know of the real reason for the labor disturbances in Canada, and elsewhere? Are YOU thoroughly familiar with the ins-and-outs of the plans which threaten a world-wide "tie-up?" This is something that should be understood by every Canadian. And every Canadian should read "The Secret of the Strikes," by Lieut.-Colonel J. B. Maclean in the August issue of MacLean's Magazine. It is brimful of startling and authoritative information regarding this great problem. Read it carefully. It starts on page 33, August MacLean's.

"The Lecturer At Large"

Stephen Leacock is one of the continent's greatest humorists. "The Lecturer at Large" is one of the best humorous sketches that he has written. It is made up of what he terms "a few painful reminiscences of the platform" in the course of his lecturing up and down Canada. Get your family around you and read the sketch aloud—it's a rare treat.

Other Big Features

"A Party in the Making." By J. K. Munro. Illustrated by William Casey. An article on the political situation, giving a great deal of inside information with reference to recent developments at Ottawa.

"Solving the Problem of the Arctic." By Vilhjalmur Stefansson. The fifth instalment of his story of the five years' explorations that he conducted for the Dominion of Canada.

"The Unspoiled Country." By Harold C. Lowrey. A descriptive article of a part of Canada which is little known to Canadians generally, Temagami.

"Petite Simunde." By Arthur Beverley Baxter. Illustrated by E. J. Dinsmore. A charming romance of the war. The author will be remembered favorably for his "Mr. Craighouse of New York, Satirist."

"The Seven Blue Doves." By W. A. Fraser. Illustrated by Charles L. Wrenn. The fifth of the Bulldog Carney series and in some respects the best. It is a mystery story.

"His Majesty's Well-Beloved." By Baroness Orczy. Illustrated by C. F. Peters. The second instalment of this splendid romantic novel of the colorful era of Charles II.

The Month's Vital Question

Turn to page 34, August MACLEAN'S, and you will find timely and interesting information regarding the High Cost of Living—a problem of large proportions.

The Review of Reviews

Here are a few of the articles chosen as the best published during the past month in all magazines:—Britain Winning Supremacy of the Air; Has Japan Two Governments?; Kaiser Employed Famous Beauties; The New Triple Alliance; Mammoth Animals in Alberta.

Over 70,000 Canadian Families Buy

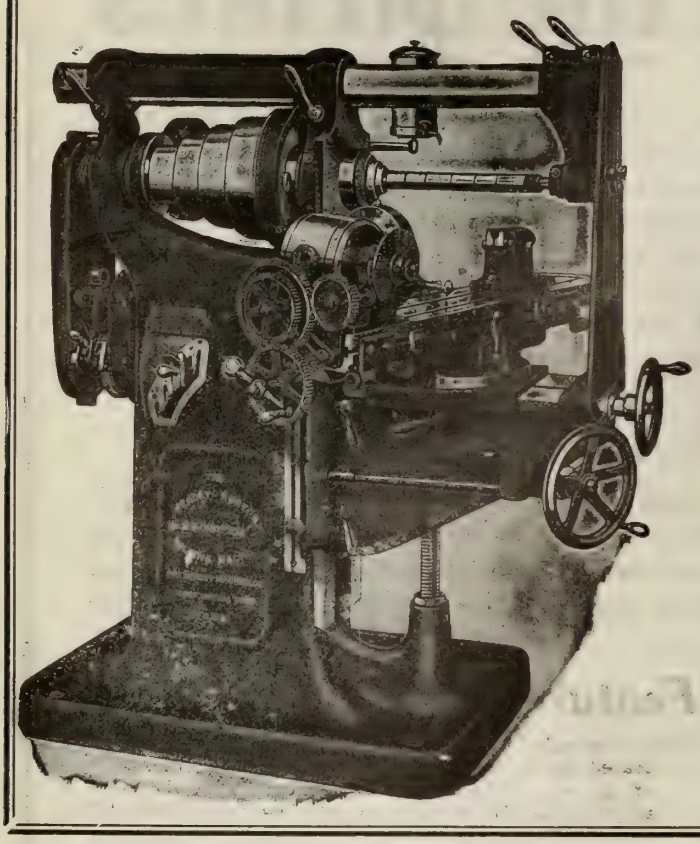
Anybody Can Operate This Miller



and Turn Out a Pile of Work so Simple to Operate is the

"HENDEY"

Skilled mechanics are scarce these days—but anyone can run a machine of its simplicity and turn out work accurately and fast without trouble.

All Feeds positive driven through gearings giving 18 changes.

This is the universal type—designed to handle all milling operations performed on machines of this character, either with regular equipment or by aid of attachments, which can be supplied for increasing efficiency and scope of machine.

SKF BALL BEARING HANGERS

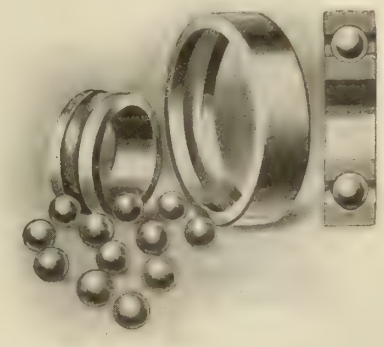
SKF

"GRÖNKVIST"

Quick Acting, Automatic Drill Chucks

THESE are a few of the advantages to be had from the use of SKF Bearings. Think of the fact that out of every three operations these bearings go through in the intricate process of converting them from raw material to the finished article on econsists of inspection, that although they run with a freedom

MONARCH SERIES CONRAD PATENT



Deep Grooved Rigid Type SKF Bearing

from friction hitherto unknown to science, they do not vary a ten-thousandth of an inch and you will faintly conceive the high degree of mechanical perfection attained in the manufacture of SKF Bearings. You will also realize why the leading manufacturers on this continent use SKF Bearings in their high-grade machines and SKF transmission in their factories.

SELF-ALIGNING BALL BEARINGS

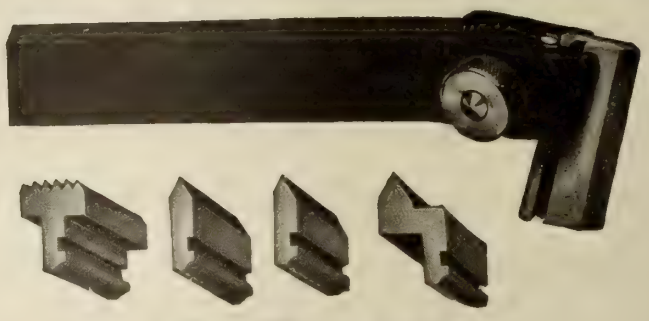
SMALL TOOLS

P. & W. Threading Tools



Chase | Single Point | Offset | Double Onset

PROMPT SERVICE

is assured at our nearest office. Place your order there to-day.

Uses the same holder for chasers and single point cutters. The change can be made in a jiffy.

A few of its advantages:

Threads can be cut very close to shoulder.

Tools are sharpened by simply grinding off top of cutter.

Combines economy with all features essential in a threading and forming tool.

Cutters have 15 deg. clearance, which experience has taught gives the longest wear in various metals.

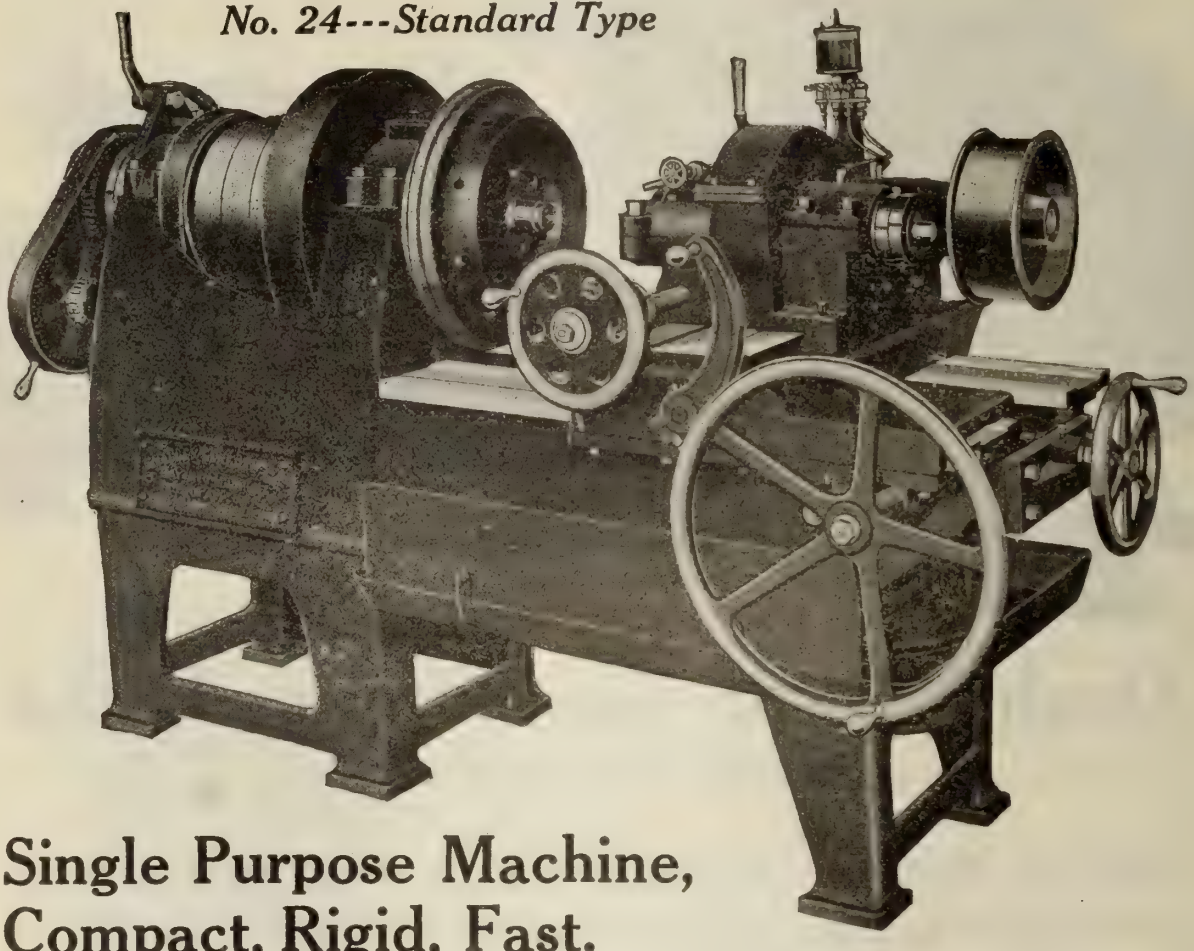
Smalley General Thread Miller

No. 24---Standard Type



Single Purpose Machine, Compact, Rigid, Fast.

The same strength and rigidity which gave our No. 1 machine the acknowledged reputation of being the greatest producer of its kind has been fully maintained in this new and improved model. Some of the features of the Smalley General Thread Miller No. 24 are: **Sturdy construction, absence of loose gears, simplicity of operation, cleanliness and small floor space it occupies.** It will mill threads with greater accuracy and speed than can be maintained by any other method.

PATENT FEATURE—The machine is equipped with a feed-tube and lead screw device (patented) which controls the thread to be milled. Thus back lashing is prevented. Thirteen inches of the thread on the lead screw is provided, giving longer life, greater accuracy and larger production. Thread can be picked up at any time or place.

The productive advantages of the Smalley General Thread Miller over all other machines of this type are worthy of investigation. Write for full details.

Purchase the Products of Canadian Mills

TO uphold the Glory we have jointly earned—to honor our noble dead—to comfort the wounded, and extend to the men returned the hand of prosperous welcome, we must cast aside all forebodings and face the future with unbounded courage and confidence and, without a shadow of doubt, declare to the World that this Nation, which was so quickly and successfully transformed to a War basis, can be depended upon to revert to Peace conditions with equal success. The buyer and seller must recognize their duty to the Nation and co-operate fully to the end that all products that can be produced in Canada by Canadian workmen shall not be purchased elsewhere.

OUR Duty is plain; Canada with Canadian labor and capital can produce, manufacture and distribute products sufficient to keep the wheels of industry turning to the limit. The song of Prosperity and Happiness should ring out all over the land. Let us sincerely pledge to the extent of our needs, to purchase materials produced in Canada by Canadian Workmen, and the result of our efforts will return to us the Blessings of a Prosperous and Happy Nation.

General View of the Plant of the Algoma Steel Corporation from the Waterfront.

Five Betts Planers in this Ohio Plant

BETTS tools are built to render service—not to sell at a price. The Ohio Locomotive Works, in which this photo above was taken, investigated the entire machine tool field before purchasing 5 Betts Planers. After a point for point comparison they found Betts tools to be the best investment.

They have had good reason to congratulate themselves many times on their judgment as the five machines are giving satisfactory service and the production obtained more than meets the rigid requirements of this plant—not only on the class of work shown here, but on every kind of a job that can be handled on a planer.

When you think of machine tools---think of Betts

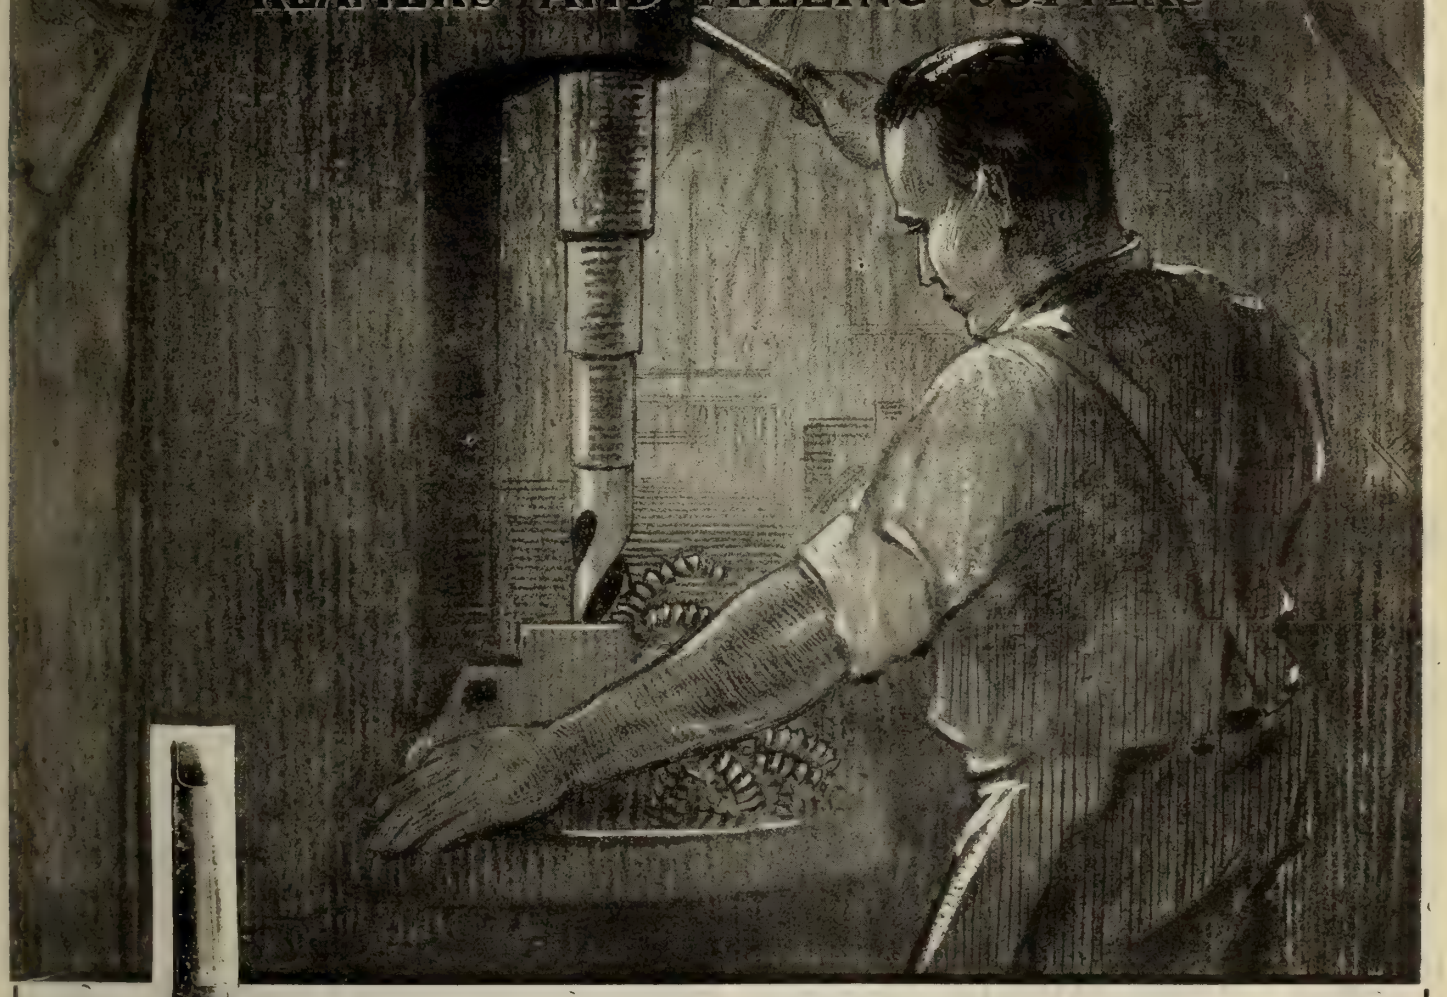
WILT

HIGH SPEED AND CARBON TWIST DRILLS, REAMERS AND MILLING CUTTERS



Quality Tools a Vital Necessity

Where there's a WILT—There's the way

Equip your plant with modern tools of the best quality. It is the vital necessity of the day to Manufacturers. Competition of the present and in the future demands it.

For your drilling, reaming and milling cutter operations, choose *WILT High Speed and Carbon Drills, Reamers and Milling Cutters.* As compared with any ordinary tool they cut faster, more accurately, require less power, require less re-grinding and give longer service—and they cost no more than ordinary tools.

Put them to the test—you'll find them best

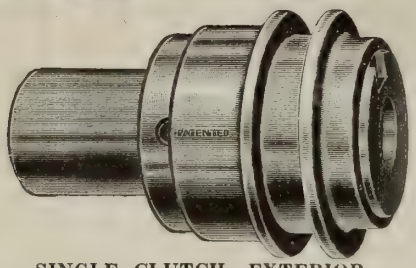
THE JOHNSON FRICTION CLUTCH



SINGLE CLUTCH—EXTERIOR

THE SIMPLEST WAY—AND THE BEST

In a clutch or any other mechanical device, unnecessary complication means trouble. Make a single part serve where two have been used before, and you have reduced by one-half the places than can break, wear or get out of adjustment. Put the cost of *extra* material into *better* material, and you have doubled the length of service.

In the Johnson clutch, this idea has been fol'owed out to its practical limits. The result is a model of simplicity in clutch construction—a few sturdy parts, each correctly built and accurately tested for the duty it must perform. This lack of complication means continuous service and low maintenance cost. Johnson Friction Clutches stay on the job.

Individuality

A GREAT MAN wrote this: "I'm called away by particular business, but I leave my character behind me." And nobody had to guess whose character it was. Even if the familiar Red Cut label should disappear there would be no doubt as to the character of the steel that remained. More than ever would the quality shine forth in the results when it was worked. Adherence to the highest standard with an unvarying uniformity has placed a well merited reputation all its own on

RED-CUT SUPERIOR HIGH SPEED STEEL

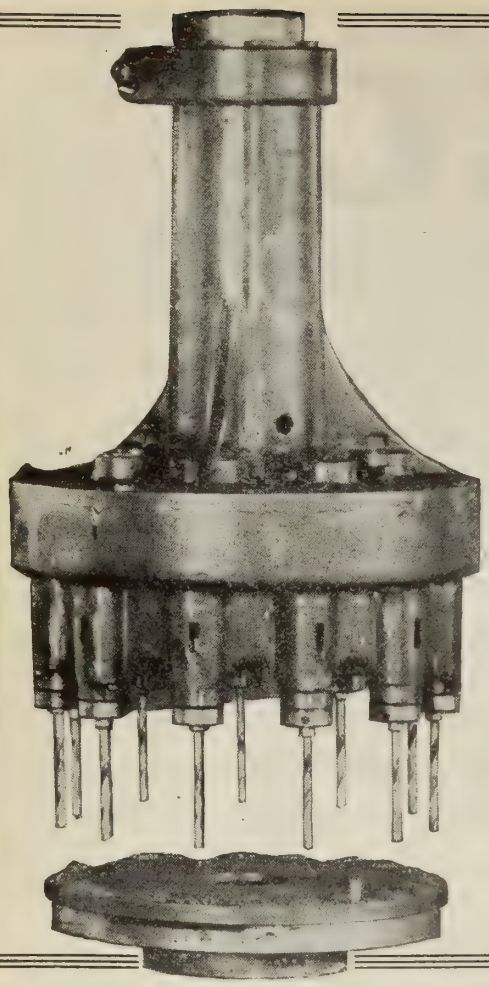
Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25%; a different method of molding them might double your production at no increase in molding cost. **We can advise you** and we have expert metal and wood pattern-makers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.
We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us.

ASK US



SPEED UP THE WORK

Rising costs are knocking the bottom out of profits these days! Materials and labor are up. No chance to reduce them. But you can speed up your work. The Hoefer Manufacturing Company has a proposition that will cut your drilling cost. Not guesswork, either, but on a basis proved by experience.

By using Hoefer Auxiliary Heads you can drill ten, twelve or more holes in the same time as one. Not only do you save the drilling time, but also the time lost shifting the jigs and raising and lowering the spindle for the extra holes.

360 manufacturers, 99 distinct lines of business—probably some of your competitors—employ Hoefer Auxiliary Heads to increase profits. They say the Hoefer Auxiliary Heads pay for themselves in 30 to 60 days.

Hoefer Auxiliary Heads are made in any multiple, arranged in any manner, from 2 up. Made by expert toolmakers and guaranteed to handle accurately the work for which they are designed.

Investigate now. Stop the leakage of dollars due to the use of single drills. Write for catalog and send blueprint of some of your work for estimate of time and cost.

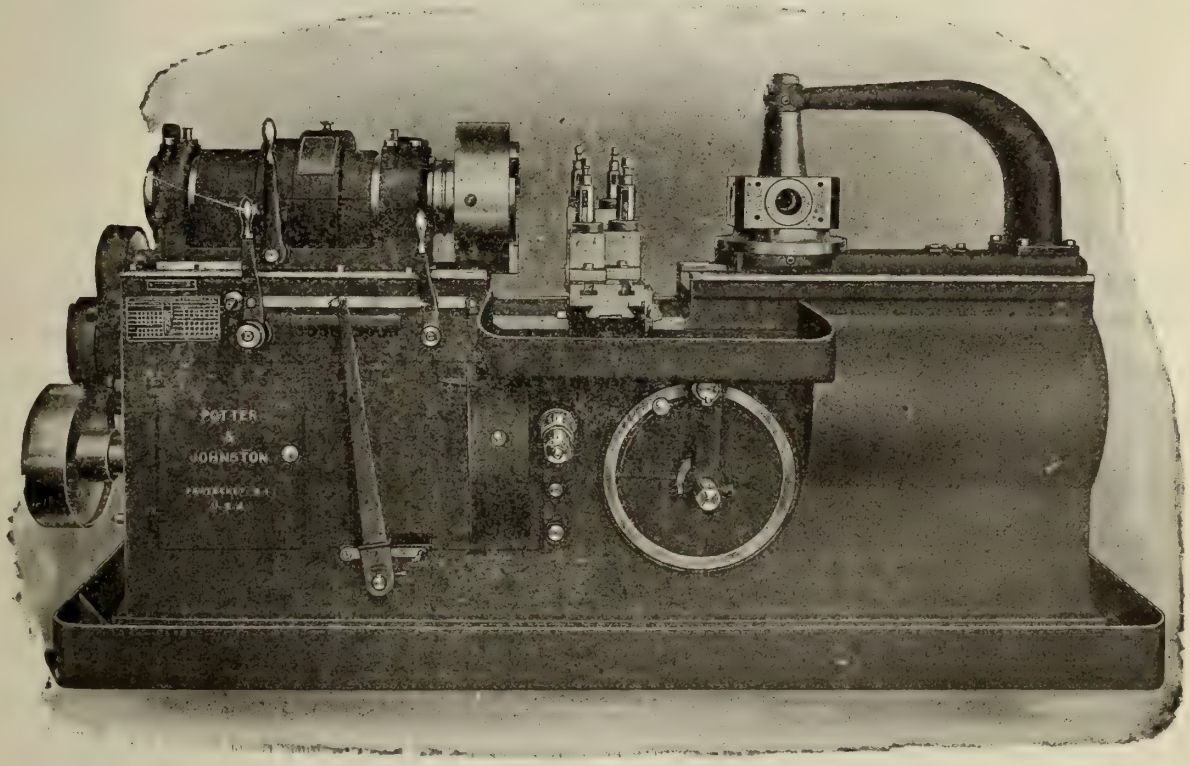
MANUFACTURING AUTOMATICS FOR ECONOMICAL PRODUCTION



6A Manufacturing Automatic

When times are dull you want to get full value from your labor—you cannot afford to do otherwise and stay in the game.

When times are busy you have hard work getting help.

A serious problem from either angle.

The solution: Potter & Johnston Manufacturing Automatics for all duplicate parts from castings, forgings, cut-off stock, up to 40 inches diameter and up to 15 inches long.

From two to a dozen cutting tools always in simultaneous operation. Instead of an operator for each machine, an attendant for from two machines to half-a-dozen.

If you have any doubts as to whether these Manufacturing Automatics will apply on your work, take it up with us and we will help you investigate.

Descriptive Bulletin 39 on request.

A WALL RADIAL DRILL

That Puts Dollars in Your Pockets

Here's a real machine tool in the wall radial drilling line for your consideration. Listen to this—the machine is made of high grade materials throughout, and the workmanship is beyond criticism. It is designed with the particular idea of maximum production, at a minimum operating expense. Entire control within easy reach makes the operators "boosters" for these machines. You can keep the dollars that may be slipping away on your wall radial drilling propositions, in your pocket by the installation of this machine.

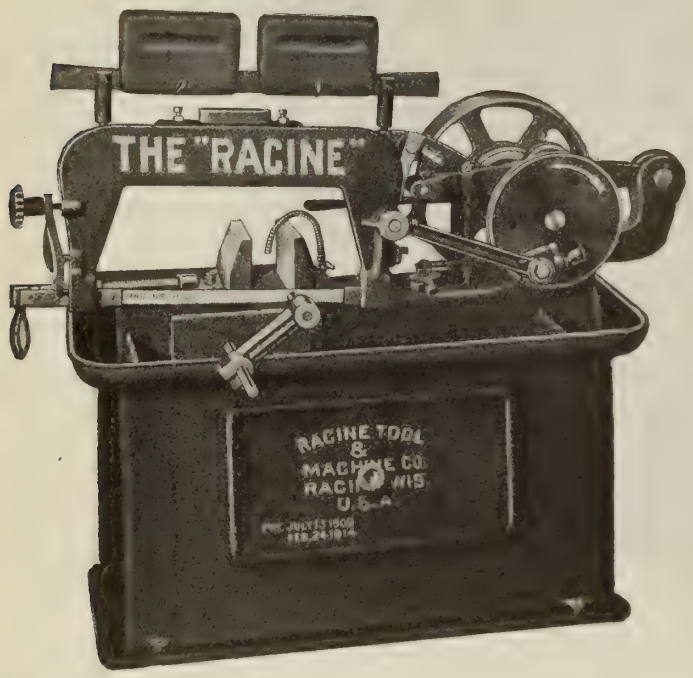
"THE RACINE"



HIGH SPEED METAL CUTTING MACHINE

Reduces Blade Expense

Aside from its ability to turn out more work than any other metal cutting machine, "THE RACINE" will save you considerable money on blades alone—enough to pay for itself in a reasonable time. The automatic lifting device is responsible for that. It automatically raises the blade on the return stroke, relieving it of all dragging or strain. This also means quicker cutting, less power used and greater production.

There are many ways "THE RACINE" will prove a big saving. Let us tell them to you.

Starrett Hack Saws make less waste

Economy of material is almost as important as economy of time—or power.

The Starrett idea is to always use the particular blade that does the work in hand most economically—to save material, time and power.

That's why the Starrett Hack Saw Chart recommends blades of different thicknesses as well as different numbers of teeth to the inch for certain classes of work. And it's the reason why you find Starrett Hack Saw blades and charts in the tool rooms of so many shops—it pays to use them.

UNION

POSITIVE DRIVE DRILL CHUCKS

The Union Drill Chuck is made in seven sizes (0 to 2 inches) with PATENT TRANSVERSE SLOT—so that drills with tenons can be inserted (see illustration). The shank of drill should be squared on two sides to enter the TRANSVERSE SLOT, giving a positive rotation to the drill independently of the jaws, permitting the jaws to centre and align the drill accurately. The drill is held absolutely true and will not slip under the hardest strain. This type of chuck will be found to give the best results on all classes of work from HIGH SPEED drilling to the hard BLACKSMITH and GENERAL REPAIR work.

A Railroad Service for the Automobile

Can We Successfully Use the Automobile in Place of the Steam Engine for Railroad Purposes? Read How This System is Being Operated With Splendid Success

By D. A. HAMPSON

WHEN the automobile entered its heyday of popularity it was freely predicted that it would soon usurp the place of the steam train for passenger service. The idea seemed to be that we would have motive power units of the automobile type, larger and much more powerful, and possibly drawing a number of cars behind it as does the locomotive. "But somehow or other, the scheme never got very far," to quote the summary of the average person who had expected such a change in transportation. There were, and are, a number of conditions adverse to the broad application of the gasoline engine to railroad work, the chief of which were the limited efficient speed range of the engine itself, the absence of a satisfactory means of building up a train speed from a dead stop, and the high cost of operation and maintenance.

However, a change has come about in the last five years. The motor truck, from an experimental machine, has grown to be the husky workhorse of commerce that we know to-day. Both in first cost and upkeep it is cheaper now than then; and designs have been evolved that adapt it to every kind of hard service. On the railroads, however, materials and supplies and labor have doubled in price, so the cost of running trains has far outreached the meagre increase in rates. Street railways and branch lines and short independent roads are fighting with their backs to the wall to make ends meet. As the natural sequence of such changed conditions the automobile has been again tried out on railroads and has proven to be quite satisfactory.

Everyone has seen the loads and overloads which are carried by motor busses on our streets and highways, in times of strikes and breakdowns and in the feverish struggle at the height of munitions manufacture, the loads that these machines carried were almost past belief. All such conveyances are bus bodies mounted upon regular truck chasses. It is reasonable to assume that they would perform creditably upon steel rails with their rated loads, a fact proven beyond a shadow of a doubt.

Fig. 1 shows a railroad job that has been running on a steam road for months. The body is a standard 20-passenger bus set upon a Reo chassis. A body of this seating capacity is four feet longer than the car frame, producing quite an overnang at the rear; in this case, the frame was lengthened to

FIG. 1—A GOOD VIEW OF THE CAR.

reduce the overhang and to relieve the rear axle construction.

Raliroad Service

Two of these motor cars are in service on a fifteen mile standard gauge road. Five round trips a day are made with one car, the other one being kept constantly in reserve or to run as second section for a peak load. Slightly over ten gallons of gasoline furnishes fuel for the day's run, with a pint of engine oil, besides the usual "oiling around" for running gear parts. Formerly a steam mixed train made three round trips a day, but this now makes two trips only, the motor train making the third and four other trips, thus providing the territory served with unusually good accommodation.

In common with many other short roads, the cost of operation is out of all proportion to the revenue even with the bunching of the traffic in a few trains. Two engine men, two brakemen, and a conductod constitute the crew in most cases, and these men have good reason to object to a time card that keeps them on the road from early morning until late at night, seven days a week. An extra train crew is a luxury not to be thought of for a minute, so it happens that the small road schedule usually narrows down to a 7 to 6 basis, to which the travelling public strenuously objects with an incessant "disgracefully poor service on this old P. & Q. road."

The motor train has come as a welcome relief to the conditions named. It has ample capacity for carrying the few passengers travelling at most hours of the day. The driver is the entire crew —he may be a serious-minded youth or a middle-aged man, or again the position may be acceptably filled by a disabled soldier. The saving thus effected over the expense of skilled men's wages is a big item. The saving in operation of a car weighing, loaded, two to four tons, as against a train of a hundred tons may be imagined, as also may that of stopping the two to take on or discharge the one lonely passenger so frequently witnessed. With the motor train, therefore, it is possible to give better train service, to extend that service to evening hours and give patrons a chance to attend gatherings that would be out of the question with the steam service. We find then that the automobile on the railroad has enabled us to do two things, i.e., give more frequent service and cut down the operating expenses. With the revenue practically fixed the showing made from the change is gratifying.

One railroad manager hit upon the scheme which is depicted by Fig. 2, a sort of a double ender, which probably has no parallel except on the mountain railroads of Central and South America, where locomotives are built to face and run either way to the front. Our illustration shows two Reo busses coupled

back to back, the total seating capacity is forty, with a possible crowding capacity of nearly double that. The beauty of this arrangement is that no time is lost at terminals in turning around, in fact, no provision for turning need be made.

Going south, engine No. 1 pulls the train, while going north, engine No. 2 works and No. 1 rests with the gears set in neutral. Stated another way, a trailer is pulled on every trip. There is ample power for the trailer at all times: its weight with twenty people is approximately 6,000 lbs., a weight that necessitates but a small draw bar pull mounted, as it is on anti-friction bearings and running over the smooth, comparatively level railroad line. There are, of course, but two driving wheels at any time, and so on a greasy rail the same slipping occurs that is true of steam equipment, but the addition of sand boxes has rid the management of this trouble.

This two car train makes a speed of forty miles an hour at points between stations. It is very popular with patrons of the road, who prefer to ride on it to riding on the mixed trains, because it is cleaner and does not stop to switch cars at stations. Where the road was once a thing of derision, the patrons now take considerable pride in it and its up-to-date equipment and frequent service.

THIS ONE WORKS BOTH WAYS.

Still another application of the automobile to railroad use is shown at Fig. 3, which shows a Reo with 15 passenger body running on a trolley road. Electric roads have suffered more than steam roads from rising costs, while the nickel remained the chief units of fares and the jitneys robbed them of more or less of their trade. Small roads find the cost of maintaining power plants a heavy burden—much greater in proportion to the power required than with the larger electric systems. It is not contended that gasoline cars are cheaper to operate than electric ones of the same weight and carrying the same two-man crew—they are not. Neither is the wear and tear of frequent starts and stops in city service less for the gasoline vehicle, on the contrary it is a well-known fact that the automobile engine and mechanism is most uneconomical in operating cost when frequent stops are made.

But it is true that the automobile engine operates at its greatest efficiency on long runs, within a limited engine speed range where the thermal efficiency is greatest. And then the cost of a motor truck is small when compared with a trolley car, also the ratio of the load carried to the deadload is far in favor of the gasoline machine. The big does not enter into the railroad automobile operation is that of tires and this does not enter into the railroad automobile at all, for the tires used are good for the life of the car, in fact the railroad wheels can be put on a new car at practically no expense by turning in the rubber tired wheels or tires alone in an exchange. Automobile weights have been pruned by the use of high class materials until the weight per horse power is but a fraction of that in use on all kinds of existing railroads.

A typical case of trolley work is the system of the average city of about 25,000 inhabitants, It has ten or twelve miles of street railway within its city limits, and usually one or more lines extending to neighboring villages; a good average would be double the trackage outside the city that was in it. The heavier and better cars are almost always run on the interurban lines, cars of 28 or 30 tons weight with four 30 or 40 h.p. motors under them. At present rates, these cars run at a big loss most of the time, the rush hour load from some factory, the holiday and Sunday crowds to a pleasure park, and the Saturday afternoon shopping crowds are the only paying times during the week. The rest of the time the cars are running nearly light but the expenses for current and the two men of the crew are just the same.

Hour after hour during the mornings these cars operate with six to a dozen passengers, and for a thirty ton car! Where power can be purchased cheaper than it can be made, there is a saving on the city lines but the suburban and interurban lines still are a drag. What is more natural than to use a motor outfit on such trackage, cutting off the electric current altogether? The outfit in Fig. 3 is one solution.

One man can operate this car. It carries all the morning and light afternoon loads that the thirty ton electric would run for. It gets away faster than the electric car. The way it can pull has been a revelation to many an old trolley man. What is of interest to the passenger is the smoothness of riding, these cars being entirely free from the bobbing of the single truck car and its disagreeable side lurching. Electric roads have much heavier grades than steam roads, but the motor car has no difficulty with these except where stops have to be made on steep upgrades. The single pair of driving wheels not having or getting sufficient traction under unfavorable conditions it is found necessary to rearrange the stops and to fix points where a start would not have to be made on a bad upgrade. A judicious seating of passengers has helped in other cases, so has sand, and so has a freeing of the rails of the grass and grease which did not bother the trolleys. There is no lack of engine power—there is power to slip the wheels on any start.

"How do you reverse?" is a question that might well be asked. Steam roads always have a Y or a turntable at the terminals. Special turntables have sometimes been used for motor cars. On trolley lines either a turntable or a Y has to be put in. Or the double end scheme previously discussed may be worked. Still another way is shown by the photo. The car is run off the end of the rails and turned as you would turn any automobile. As municipal authorities might object to this (although the wear and tear on the street is no more than with heavily loaded horse drawn vehicles with narrow tires) it is now proposed to pave a thirty-five foot square at the track end and turn around on this, by so doing making a good all weather area for car use without in any way detracting from its function as a highway.

It might be inferred from the foregoing that the automobile for railroad use was a perfect, fool-proof piece of rolling stock. It is not. With decent handling and a little attention to well-known vital necessaries, it will do plenty of work and do it cheaply, quickly and with cleanliness. But if neglected as the farmer did his Ford, by running it without oil or water (and then pronounced it a "lemon") the railway automobile will lay down too. However, this is a mechanical age and all men have more or less latent ability in that line, so it is a simple matter to pick out a faithful, serious-minded person to run such cars and give them service attention.

Where rough tracks are encountered the wheel and axle bearings get some pretty hard pounding and these should have weekly inspections. Overloading is an unpreventable evil on the railroad as in ordinary motor trucking service, and this hastens the renewal time for bearings. The same is true with cars in rail-

way service; but as the bearings are standardized, are comparatively inexpensive, and can often be changed between trips, this item is a minor one. These are the only parts found to suffer from the exacting requirements of railway service—quite negligible alongside of average rolling stock repairs.

All of the work with which the writer has been connected, and the experiments, have been made with the Reo model F, commonly called the "speed wagon." The

TURNING AROUND AT THE END OF THE LINE.

time-tried sturdy motor of these trucks has been found fully equal to the demands made upon it, through hauling several times its rated load and under guaranteed conditions. Without holding any brief for Reos, the writer feels under obligation to add that the performance of these trucks, the unique interchangeable system of manufacture, and the reasonable charges for parts should commend them to all prospective users of light trucks for this class of work.

Sharpening the Coventry Screwing Die*

It is Quite Possible That We Have in This Country Some of These English Die Heads in Operation, so for Readers' Benefit We Publish an Account of Method of Sharpening

THE following notes are written for operators who are new to the use of the Coventry diehead and those who have been unable to get the satisfactory results which are generally obtained.

The older forms of screwing dies could not be sharpened after wear. This is true, at least practically, of the half-die, split nut and solid nut forms. It was extremely difficult even to make them correct when new. The engineers at Alfred Herbert's works in Coventry had to face the fact some years ago that the development of the capstan and turrent lathes, on which they at first wished to concentrate their energies, was impeded by the inferior design and quality of cutting tools generally obtainable on the market. The screwing die was one of the chief deficiencies, and they were practically forced to take up the whole question of design of dies and dieheads.

The British screw manufacturers met the difficulties in their own way, and many years ago produced bolts, screws and nuts in all forms and sizes of excellent accuracy and at wonderfully low prices. Manufacture, in the proper sense of the term, is the continuous production of large quantities of identical things. It allows of highly specialized methods, management, supervision and training of labor and special machinery which are not always applicable to the production of a limited number of pieces in the engineering works.

The diehead required, in order to get the full advantages of the new lathes, was one which (1) could be quickly and accurately fixed in the turret, (2) in which the dies were as free cutting as any other lathe tool, (3) in which the dies could be sharpened quickly and accurately to the best new condition, (4) in which the dies would stand prolonged cutting work and many re-sharpenings, (5) in which the dies were positively and reliably self-opening at a set point, and (6) in which the parts were interchangeable.

These results were obtained after a great deal of work and expense, and now there is hardly any tool more accurately made and more widely used than the Coventry diehead.

Sharpening the dies is not a difficult job. Ten of thousands find it no trouble, but there are always a few who require some explanation. These few have not, perhaps, had the opportunity or do not take the trouble to master the mechanical principles involved. The sharpening is not only easy, but an almost automatic process if the right methods and appliances are used. If other methods are used it is an almost impossible job. A highly skilled man who thoroughly understood the forms of cutting tools would not think of wasting hand work time on what he would at once see to be a job for jigs and machine grinding.

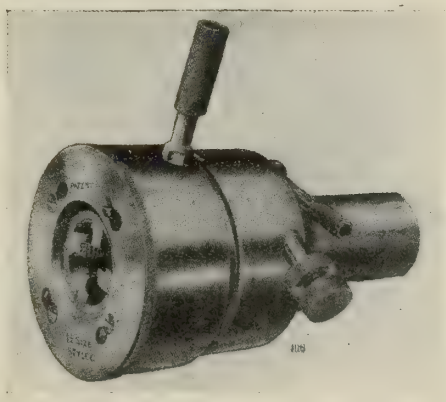

FIG. 1—GENERAL VIEW OF THE DIEHEAD.

The method is stated in a very few lines of print in standard form instructions. But we find by experience that while the terse straight style is enough for the skilled or experienced, some explanation is necessary for others.

A general photographic view of the diehead is shown in Fig. 1. The handles for changing from roughing to finishing cuts (where two are necessary), adjusting the finished size and closing the dies, are familiar to users. The dies are plainly seen in this figure in cutting position. A general photographic view of a die, removed from the head, is shown in Fig. 2, and will be useful in understanding the line drawings in the following figures. All four dies, for any size, are alike except on the thread face, where they differ so as to form four stages in the continuous coils of a screw thread.

The analysis of the form of the die can only be followed by separate views of the several surfaces, such as are roughly drawn in Figs. 3, 4 and 5. At this point, however, we may indicate where the mistakes begin when they occur at all.

A man takes out the four dies, as in Fig. 2, and finds one or some of them worn on the cutting edge. He sharpens those that are blunt, and says to himself, "It is no use sharpening things that are not blunt; that would be foolish and a waste of time." That seems to be good logic, but it overlooks the main principle, viz., that the dies are not four independent cutting tools, but one compound cutting tool in four parts. All four, when in action form one tool with four edges in strict relation to each operation, which is not always neces- equally until the bluntest one is sharp; because they must not only be all sharp but all the same size in order to divide the cutting work equally amongst them. They must be equal in size as well as equally sharp.

Another kind of mistake follows. A man takes out the four dies and sharpens them equally and properly. On putting them back he finds that they cut like new. He repeats this several times, with equal care, but finds they gradually depreciate in cutting efficiency. This arises from neglect of a second grinding operation, which is not always necessary, but becomes necessary in proportion as the repetition of the first grinding operation wears away the die and alters its shape. This will be explained in the following:

Fig. 3 shows a direct side view of the die, only face H need be ground. The rectangular, as shown by the outside line. Line F—G will coincide with the centre line of the piece to be screwed and of the lathe. The line K—L shows

*From "Machine Tool Review."

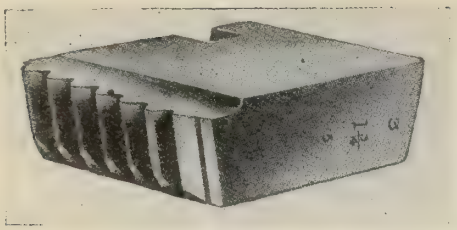

FIG. 2—GENERAL VIEW OF A DIE.

the inclination of the thread in relation to the centre or axial line, and does not concern our present purpose. The die is ground in a tapering direction, creating a face H—the vertical direction of this taper being shown in Fig. 4 and the horizontal direction in Fig. 5. When the die gets blunt face H is ground until the cutting edge is restored, therefore face H gets larger in area at every grinding. H is a clearance face and a means of forming an overhanging cutting edge, so that when the die touches the rod the sharp edge will enter the metal and cut out a space which will leave a thread. This cutting edge is created from two sides; the clearance face H and the cutting face J. Fig. 2 shows the cutting face as a recessed part tapering from the top of the dies body at the back to a lower position at the front. Fig. 3 shows the cutting face as a line J which crosses the line F—G at a point indicated by E. E is the middle point in the cutting edge.

A difference will now be noticed in Figs. 2 and 3. In Fig. 3 the clearance face H is of relatively larger area, the first partial thread is more to the back of the die and at the same time the cutting face J is lower in the body of the die. This difference may be considered as the difference between a new

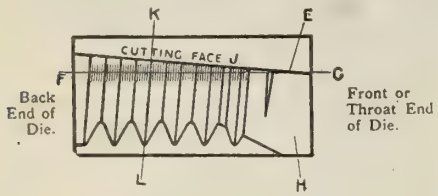

FIG. 3—DIRECT SIDE VIEW OF A DIE.

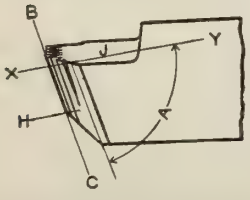

FIG. 4—DIRECT FRONT END VIEW OF A DIE.

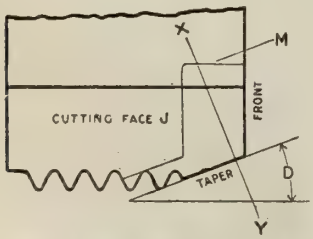

FIG. 5—TOP VIEW OF A DIE.

die (Fig. 2) and a die (Fig. 3) that has been in use for some time and has been ground properly. The difference between a new and a much-used and sharpened die is that the line J (Fig. 3) gets to a lower position in the body and the point E moves to the left.

For the sole purpose of sharpening the die, only face Hneed be ground. The roundness or bluntness of the edge is removed by taking metal off H only. A necessary consequence of this sharpening, however, is to leave the cutting edge above the line F—G. Then the edge will not cut because it is too high, just as a turning tool will not cut if placed too high in the slide rest. For this reason it becomes necessary to grind down the cutting face J.

The cutting edge extends a little to the right and left of E (Fig. 3). E is the centre of the length of the cutting edge, hence it is possible to sharpen the dies several times without seriously impairing their cutting efficiency. That will be the case especially if the sharpening is done as soon as the least bluntness appears and when very little grinding will be necessary.

It is good practice and economical in all ways, to keep the dies sharp. This is true of all cutting tools. There is an old workshop saying: "Don't sharpen your tools, keep them sharp."

The line B—C indicates the direction of the thread; D the taper of cutting edge or its angle in relation to the line F—G on a horizontal plane, and A the cutting angle. The cutting angle is formed and measured on the two faces H and J; the direction of the H line being shown on Fig. 4 and that of the J line by the line X—Y on Fig. 5.

When the die is very much worn away by repeated grindings its cutting qualities will be maintained. It will last a long time but not for ever. The disadvantage is that as the cutting edge goes back the die would not cut so close to a shoulder. This can be remedied by grinding away the die body as indicated by line M, of course only to the necessary extent.

The back threads, shown at the left of Figs. 3 and 5, do not cut, but act as a guide and smoother on the thread after it is cut. All the cutting is within the limits of the taper line on Fig. 5.

In grinding it is necessary to use the jig specially made. The four dies are ground at once, clamped in the jig in their proper order. If care is taken to use the right jig and to place the dies properly the sharpening is easy and the correct angle is obtained automatically. A special graduated gauge is made for testing the point E to indicate when grinding the face J is necessary and to grind it correctly. All the four dies must be ground on the face J equally. These jigs and gauges are not included with every diehead because one set will serve for a very large number. One set is necessary whether the dieheads in use are many or few.

An English scientist declares that insomnia may be cured by removing excess moisture from the lungs. To put his theory into practice, he has devised a small machine for supplying warm, dry, filtered air, which the patient then breathes through a nose tube secured to the head with tape. The process is said not to be uncomfortable.

Saving controller contacts from damage by arcing is the object of a European inventor. In series with the contacts he connects hot-cathode rectifier tubes, whose heating circuit is broken by the switch arm in advance of the main circuit. The momentary interruption of the current prevents any arc formation.

The number of German airplanes destroyed by the French aviators and the members of the Lafayette escadrille for the ten months ending October, 1917, was one hundred and twenty over the French lines, and three hundred and ninety-seven over the German lines—all total wrecks.

For a long time the waste steam from steam-engines has been turned to good account, but there have been difficulties in the way of using the exhaust gases from a gas-engine as they readily attack the metal of the conduits. However, the difficulty is being overcome, for a New Jersey candy factory has an installation in connection with a sixty horsepower engine which is used to heat the factory. The gases pass through an economizer made of cast-iron, with the passages to the different sections staggered so that all parts are heated for the whole length. Water circulates in jackets surrounding the gas passages.

The hoe-blades are fixed to the lower ends of arms suspended from a crankshaft. Bars extending from the hoe arms to rocker arms at the rear of the machine regulate the movement of the hoes, imitating the strokes and motions of an ordinary hoe worked by hand. The crankshaft that drives the hoe-blades is connected by a chain, sprocket-wheels, a gear-shaft and gears with the main or driving axle. The device may also be arranged to be driven by power from a small gasoline engine, but it is not very hard to run by hand.

ERRATA

In our July 31 issue, an page 126, we illustrated an electric storage battery truck, which we mentioned was handled by the Electric Storage Battery Co., of Philadelphia. This was an error, as the truck shown was made by the Baker R. & L. Co., of Cleveland, Ohio, but was equipped with a battery of 24 cells MVY-17 Ironclad-Exide, which are manufactured by the Electric Storage Battery Co., of Philadelphia.

Novel Portable Electrical Drill Heads

Both English and German Type of Portable Electric Drill Head is Herein Described. The Unprecedented Range of These Tools Make Them Exceedingly Valuable in Many Classes of Work

By FRANK C. PERKINS

THE accompanying illustration, Fig. 1, shows the operation of a novel English portable electrical drill head, developed at Bootle, near Liverpool, England, while in drawings Figs. 2 and 3 and photograph Fig. 4 may be noted the construction and use of a unique German portable tool head in cylinder boring; also German tool head with pivoted tool seat and telescope shaft, driven by an electric motor at the works of the Allgemeine Electricitats Gesellschaft at Berlin. It is claimed that this portable electric drilling machine has an unprecedented range, and can be instantly adapted, with the minimum amount of trouble, to work under almost any conceivable conditions. The motor may be operated in any position on the ground, or speedily detached from the carriage and slung up in the air, without the use of stay ropes, steadying gear, or platforms.

It is pointed out that there are no flexible or telescopic shafts, knuckle joints, or similar devices for transmitting the power from the motor to the drill. The drive is practically direct, and the important advantages of this arrangement will be fully appreciated by those who have had experience with the earlier methods. It is a sound mechanical tool with no complicated gearing likely to get out of order, and is of such a solid character that it is almost impossible, with fair wear and tear, for any part to cause trouble.

It is maintained that the whole machine may be easily managed by one man, who can start and stop instantly, without removing his hand from the drill head. The field for the employ of this drill is almost illimitable. Many steamships with electrical equipments carry them, as the engineers have at command an appliance enabling them to carry out with neatness and despatch the repairs usually necessary in the event of a breakdown.

This novel English portable electrical drilling machine consists of an electric motor, sliding shaft, and universal movement drill head. The motor is carried on two horizontal centres, by a frame which may be moved at will, in a complete circle, on the carriage proper of the motor. The carriage itself is furnished with suitable handles and wheels to permit of easy movement from place to place. The motor can be instantly removed from the carriage and suspended in a stirrup or bow provided with the outfit, when required to suit the working conditions. On the top of the motor is a bracket carrying a hollow shaft. This hollow shaft is provided at one end with a spur wheel, which is driven from pinion on armature shaft. Through the hollow shaft slides a long shaft, the extreme end of which is connected with the drill head. The long shaft is slotted for nearly its whole length, and this slot fits a key on the inside of the hollow shaft. Thus the motor drives the hollow shaft by means of the key and slot, and the motion is transmitted to the drill head.

The drill head is constructed with two pairs of bevel wheels (four wheels in all) in such a manner that the drill may be turned through a complete circle in a plane at right angles to the long shaft,

FIG. 1—ENGLISH ELECTRICALLY OPERATED PORTABLE DRILL IN OPERATION.

and through an almost complete circle in the same plane as the long shaft. The switch for stopping and starting is fixed direct on the drill head, thus giving instant control to the man who is drilling. The special universal worm-geared drill head, combined with an adjustable stand, can be coupled to the shaft of standard drill when specially required for tapping as well as drilling.

It is stated that this portable electrical drill will drill holes up to 1½ in. diameter in steel. The motor is 1½ brake horse power, which will take approximately 1,300 watts. This is 1.3 B.O.T. units per hour. The cost of electrical power per B.O.T. unit in most towns in England, from corporation supply, averages 3 cents. On this basis the drilling machine will cost 4 cents per hour. Where electrical power is taken from private firm's own plant, as would be generally the case, the cost would be less than this, and would vary according to the efficiency of the plant. The motor weighs 240 lbs. and carriage 138 lbs., while the weight of the shaft is 24 lbs. and the drill head weighs 44 lbs.

It is claimed that this machine has been very largely adopted by many of the foremost engineering firms in the United Kingdom and abroad, being used for a variety of purposes, embracing bridge-building and general constructional iron work, shipbuilding and ship repair work, locomotive and stationary engine building and tramway track work, also for colliery work and general engineering of all descriptions.

It is held by English engineers that this electric drill combines in a greater measure than any other machine of its class, the advantages of a fixed and portable drill. It is an excellent substitute for ratchet and pneumatic drills, the latter, owing to their excessive cost in up-keep, together with the heavy cost in application, are being rapidly superseded by electric drills.

As above stated, it is direct driven and all flexible shafts, knuckle joints and similar contrivances are dispensed with, and the simplicity of operation is thereby increased enormously, whilst loss of power in transmission is reduced to a minimum. It is under instantaneous control, the switch being fixed on the drill head or contiguous thereto, within reach of the operator. One man can easily handle the machine. The universal movement drill head and sliding shaft enable the apparatus to be worked in practically any position.

In the operation of this English outfit, with its carriage, sliding shaft and universal movement drill head, the motor is series wound, this being found preferable to the shunt wound type, the power absorbed being in proportion to the work done. The motor is carried on two horizontal centres by a frame which may be moved in a complete circle, the whole being mounted on a carriage furnished with handles and wheels to permit of easy movement from place to place. If necessary the motor can readily be removed from the carriage and suspended from a stirrup or bow.

On top of the motor is a bracket carrying a hollow shaft fitted at one end with a spur wheel, which is driven from pinion on armature shaft. Through the hollow shaft slides a long shaft, one end of which is connected to the drill

head. The long sliding shaft is slotted for nearly its whole length and this slot fits a key on the inside of the hollow shaft. Thus the motor drives the hol-

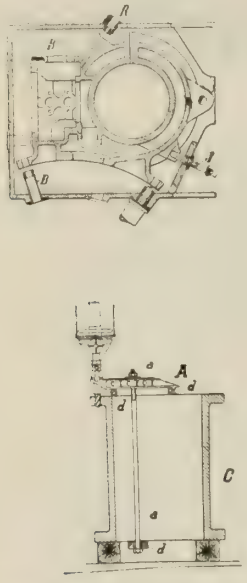

FIG. 3—GERMAN PORTALE TOOL HEAD IN CYLINDER BORING.

low shaft, and by means of the key and slot the motion is transmitted to the drill head. The gearing on the motor and drill head is entirely covered, thus protecting the workman against accident, and all terminals are protected. The machine can be made reversible for tapping. Arrangements are in progress for fitting the drills with a variable speed attachment, where required.

The special hand electric drill is one of lightest and most useful machines in service and it can be coupled up to existing lamp holder or wall plug and controlled by small switch attached to the body of the drill. Its applications are numerous, principally for direct drilling as a breast drill, or for working in a drilling pillar with ratchet feed. It is capable of working at any angle and in practically any position. One of the handles can be removed to enable the machine to be operated in confined places.

Its capacity largely depends on the nature of the work. The motor is capable of drilling holes up to ¾ in. diameter in metal, but under favorable conditions holes up to ⅞ in. diameter can be drilled. Its speed is 1,300 revs. per minute on motor and 150 revs. per minute on drill spindle, and holes ½ in. diameter can be drilled through ½ in. plate in 50 seconds, or ⅞ in. diameter in 80 seconds.

This English drill can be used for drilling, reaming, tube expanding, milling, grinding and tapping, and is specially adapted for drilling in positions where stationary machines cannot be employed. In order to obtain the maximum efficiency of the drill, it is necessary to use high speed tool steel which is self-tempering and continuous cutting when nearly red hot. It therefore requires less grinding, and the rate of drilling is much higher than can be obtained with ordinary tool steel.

AIR SCREEN FOR FURNACE WORKERS

An account was recently given in a German technical paper of the latest methods employed in Germany for screening furnaces. Workers required to examine the glowing material at frequent intervals suffered a great deal from the excessive heat radiated, and various devices have been tried to minimize the ill effects. For example, hollow water-cooled furnace doors have been tried, but obviously they afforded protection only while closed. Again, devices have been installed for drawing off the hot air in front of furnaces by centrifugal exhausters placed in front of the furnace opening. An objection to these is that workers are subjected to great variations in temperature prejudicial to health. According to the article quoted, the most effective device is to fix immediately behind the furnace door a narrow, oblong nozzle, through which cold air is blown upward, thus interposing a screen and relatively cool air between door and furnace. This arrangement is to give adequate protection to the worker, and has the incidental advantage when the doors of the furnace are opened, the escape of flame is checked.—Engineering and Industrial Management, London.

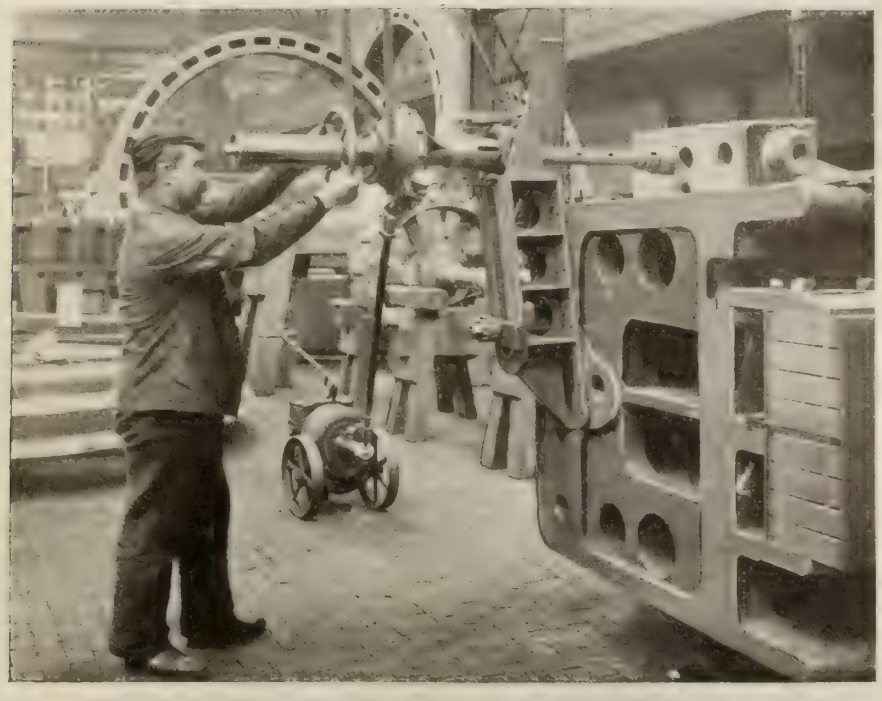

FIG. 4—GERMAN PORTABLE TOOL HEAD, WITH TELESCOPE SHAFT OPERATED BY ELECTRIC MOTOR.

AIR RESISTANCE OF TRAINS

The advance of aeronautics has, among other things, made engineers generally pay more attention to the importance of so shaping objects which have to move at high speed through the air that they shall offer as little resistance as possible. Anyone who puts his head out of the window of an express gets some idea of the pressure of a sixty-mile-an-hour wind, but he may not give a thought to the fact that the same pressure is helping to retard the progress of the train. It has been calculated that the flat front of a locomotive smoke-box offers sufficient resistance to absorb about 32 h.p. at 60 miles an hour, and 75 h.p. at 80 miles an hour. By giving the smoke box a hemispherical front the figures could be reduced to 7 h.p. and 15 h.p. respectively—a very important decrease. By reducing the width of the buffer beam, avoiding pockets in the sides of the engine, giving the tender sides and a roof of the same height of the carriages, decreasing the gaps between carriages, stream-lining accumulators and air reservoirs and making windows as nearly flush as possible, train resistsance would be greatly lessened. A tapering tail, such as is fitted to a racing car, would have good results, since the suction at the rear of a train is very considerable, but there are practical objections to its use. Experiments made in America showed that a flat-ended electrically propelled carriage could not be driven at 50 miles an hour by power which sufficed to give a similar carriage with parabolic front a speed of over 75 miles an hour. This seems to show that there is plenty of scope for reducing the power bill of our railways by applying to trains some of the care which is expended on designing the lines of a fast steamship.

One of the most efficient lock nuts for small bolts is a piece of sole leather or belt leather. Bore a hole in a small scrap of the leather, and screw it on the bolt just outside the iron nut. If the leather nut is a tight fit, the iron one will never rattle off.

The Various Mechanical Properties of Steel

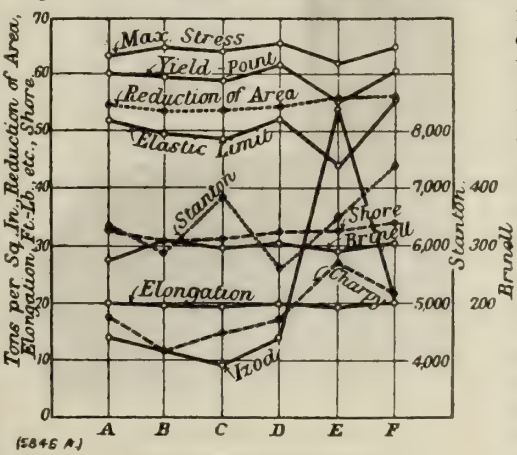
Taking Up the Consideration of the Question of Brittleness. Together With Investigation of Failures of Various Kinds. A Paper of This Nature on Steel is Especially Valuable at the Present Time

By W. H. HATFIELD, D. Met. of the Brown-Firth Research Laboratory, Sheffield, Associate Member

ULTIMATE success in ensuring the safety of parts constructed of steel is dependent upon a sympathetic collaboration of the engineer and the metallurgist. A perusal of recent publications leaves the definite impression in one's mind that at the present moment engineering design has hardly attained the position in which it can be considered as a subject for purely mathematical treatment. We have much to learn, not only concerning the distribution of stress in the different parts under working conditions, but also of the actual mechanical and physical properties of the steels when in the diverse conditions under which those various parts are called upon to perform their duties. The author hopes in this paper to extend somewhat the data at present available in this direction. In a recent paper, Dr. Rosenhain, F.R.S., and Mr. Hanson* made the following statement: "For this purpose an impact test has been used, for, although it is recognized that conditions under which failure occurs in boiler plate possess no apparent resemblance to those of an impact test, yet experience has shown that materials which give a low figure under an impact test are liable to fail under apparently static conditions." It will be seen that the authors quoted seek to determine the safety of a part under static conditions by the employment of a dynamic test.

One can, however, appreciate the question at issue in their minds, and it is hoped that this paper may throw a little light on such matters. Another recent statement, in this instance, by Dr. Arnold, F.R.S.** has a bearing upon the subject under consideration. He states: "In fact, no matter how dangerously brittle steel may be from chemical or physical causes, if such causes have coproduced a high elastic limit, the Wöhler test indicates the steel to be quite safe if stressed well short of that limit, when, as a matter of fact, it is inevitable that the steel must certainly rupture soon or later under stress theoretically quite safe." The author's reply to Dr. Arnold would be that any theoretical conclusions of the type to which he is referring must be based upon insufficient data. If a part is not stressed beyond its elastic range it must necessarily successfully withstand the stresses upon which it has to deal. It is considered that Professor Unwin, F.R.S., adequately deals§ with the subject in the following words: "All the published experiments on endurance tests have now been brought together and reduced to common measure, because the subject of safe limits of stress, especially in bridges, must, before long, be reconsidered, and because, while experiments of this kind take a long time to make, it is the number and the consistency of the results which are most impressive. A few results of bars breaking with comparatively small stress may be put aside as possibly accidental or abnormal, but here are four completely independent series of researches by different observers

Fig. 5. TESTS ON SIX STEELS 60 TO 65 TONS



ILLUSTRATIVE CHART.

(Wöhler, Sir Benjamin Baker, Bauschinger and Spangenberg) with stresses of different kinds on very different materials, and the whole of the results are singularly consistent. In all cases the number of repetitions of loading the bar will bear diminishes with increased range of variation of stress."

One might continue with advantage, to quote Professor Unwin's summing up of the data extant at the time at which he wrote, but those interested may refer to the original at their leisure. The author has always considered Professor Unwin's reply as an adequate commentary on such statements as those already quoted.

It is clear that there is a safety range of stress in which any given material may be stressed for an indefinite period. There is obviously a minimum range of stress which, over a long period, will produce rupture. However long this latter period may be, it is clear that whilst on more or less empirical calculations the stresses may have been shown not to exceed the elastic limit of the part under consideration, it is certain that some local piling up of stress must have taken place to produce rupture. If we now supplement the work to which Professor Unwin has referred with items from recent investigations, it is possible to obtain a more complete picture of what is happening. The work of Dr. Coker and others upon unequal stress distribution during recent years has done much to indicate the insufficiency of some of the empirical calculations upon which design has depended so much in the past.

The researches of Rosenhain and Ewing, and others, with regard to the development of slip-bands and the commencement of failure of crystalline metals, have done much to explain the effect of local accumulation of stress. It will be seen from these remarks that it is considered that, given reliable material, it should be possible, in the course of time, when our data are more complete, to so determine our factors of strength that the different parts of our various mechanisms may be perfectly reliable.

The engineer is familiar with the properties of steel, in the first place by actual experience with it in service, and in the second place by the results obtained from different mechanical tests to which such materials are put. The mechanical tests at present available may be recapitulated somewhat as follows. The static tests include tensile, torsion, bend, and Brinell. The dynamic tests include the Izod, Charpy and Fremont impact tests; the Stanton repeated-blow test, the Sankey, Arnold and Wöhler alternating-stress tests; the Shore scleroscope should also be included in this category. There are also the different wear tests, such as those devised by Dr. Stanton, Mr. Saniter, and others. There are other tests, but those just mentioned represent the ones which the author employs in his (different) investigatory work.

Later in this paper will be found instances of results obtained by the use of them, and in Appendix I will be found the size of test-bars employed, together with a statement of the detailed conditions, so that direct comparison may be made with similar tests performed by other investigators. The author would at this stage take the opportunity of emphasizing to engineers the danger of crediting any particular types of test with predominating importance. In his opinion, the tensile test is fundamental, but all the other tests are valuable as bringing out in each case data not other-

§"The Testing of Materials of Construction," page 355, 1899 Ed.

wise fully disclosed concerning the properties of the steel under examination.

The Investigation of Failures

As regards failures in service, the author's experience is that there is frequently some obvious cause. Whether or not the cause is obvious, it is, of course, existent. The fugitive nature of the explanations of some failures which he and others have experienced is the real reason for the presentation of this paper. Whilst discussing failures in service, it is well to point out that the explanation of failure is frequently assisted by examinations of examples which have done excellent service. Too little examination is made of the latter, and it is frequently the case that many features of failures are considered to be bad ones, which would most likely be cancelled out by the same features being discovered in excellent examples. When cases come to the Brown-Firth Research Laboratories for investigation, the following procedure is adopted. In the first place, the design of the part and its relation to other parts in the mechanism in which it serves, are carefully studied, together with the actual conditions of service, that is, the magnitude and manner of the stresses the part is called upon to withstand. In this preliminary investigation some idea is obtained as to the possible mechanical causes of failure. The manner in which said failures would be assisted by inherent undesirable characteristics in the steel is next investigated. The chemical composition is determined to indicate the quality of the steel; the microstructure is examined to determine the thermal treatment to which it has been submitted, and the microstructure is developed with a view to determining the homogeneity of the mass. The mechanical tests, including an adequate selection of the previously enumerated ones, are performed. For purposes of comparison a companion examination of a successful part is put through wherever possible.

As a result of numerous investigations, failures seem to place themselves in different categories. Treating the matter broadly, there are two types. In the first one, failures would be included where the material has rightly been assumed by the engineer to possess strength and freedom from defects, but when the material unfortunately did not merit his confidence, that is, the material has failed to live up to reasonable expectations. In the second category, would be placed the wide range of cases where subsequent examination has shown the material reasonably to possess properties which the engineer associated with it, but where failure has obviously been due to insufficient knowledge or to too empirical treatment on the part of the engineer with regard to the stresses with which he had to deal.

In the first category one would include cases where the steel is put to work in the wrong condition; where it has received faulty heat-treatment; where it has been put to work in an unstable condition; and lastly, where the part has been placed into service containing undiscovered actual defects. In the second category one must include bad design; imperfections of the technique and production; abnormal stressing (shock, deformation leading to overstressing, etc.); an imperfect knowledge of the full properties of the steel by the engineer; and lastly, an imperfect knowledge of the distribution of stress in the parts under consideration.

Fatigue failures, so called, may come under either category, that is, the steel may be well below the requirements in strength, or the part may be too weakly designed to withstand the repetition of stresses which has to be encountered. There are two further sources of failure which it is considered should also come under the second category, namely, wear and corrosion. The author recently investigated a very serious case where the failure of a shaft through corrosion would have been prevented had the engineers responsible appreciated the more simple causes of corrosion. The question

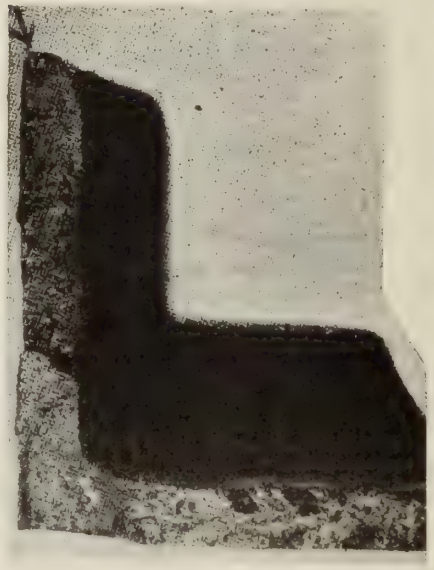

FIG. 1—A FRACTURE.

of wear is naturally a matter definitely within the field of the engineer, although the metallurgist must take some responsibility.

Different cases of past failure which have been thoroughly investigated are of considerable interest. At times also such cases are aggravating, since, as years pass along, new methods of approach and means of testing are developed, from which, could they only be applied to some of the past cases, clear explanations might possibly be provided of important cases which are even now only improperly understood. Whenever possible some of the material of such important failures should be retained so that in years to come some of it can be forthcoming to form the subject of subsidiary helpful investigations in the light of more recent knowledge. It is stated that the Greeks raised an altar "to the unknown God"; it is our practice always to retain a suitable piece of steel for submission to that new and at present unknown test, which it is hoped will some day be devised, capable of giving information which at present is absent from our tests. A few of the types of failure at present under discussion may be quoted.

Some little while ago the author read with considerable interest a paper by Mr. Sidney Houghton* on "Certain Failures of Steel Boiler Plates under Pressure." Mr. Houghton surveys and discusses a number of cases of failure, and apparently comes to the conclusion that we are yet without a satisfactory explanation of some of the most serious causes of failure in that field. The author has carefully followed many of the cases to which Mr. Houghton refers, and he is entirely of the same opinion. In the discussion of this paper Dr. Stead, F.R.S., described a very interesting case of a boiler-plate burst under pressure. It was found that there were many hundreds of fine hair lines running from the rivet holes, yet curiously there were many good features about the plate. The analysis would be considered satisfactory, but the carbon was as low as 0.09 per cent. The maximum stress was 24 tons, the elongation 30.7 per cent., whilst the reduction of area was 64 per cent. Dr. Stead stated that, in his opinion, the yield was probably about 12 tons. It is recorded that the microstructure was good, and that the non-metallic inclusions were not pronounced. One very interesting feature of Dr. Stead's investigation was the alternating-bend test to which he submitted some of this material. A value of 733 reversals before fracture was obtained, which was quite good when compared with the value he states for good English plates, namely, 760 to 970. This alternating-bend test, coupled with other considerations, would certainly point to the material being by no means in a brittle condition. Dr. Stead was not dogmatic in his conclusion as to the cause of failure in this instance, but was inclined to think that the cracks were produced by the maltreatment of the material in the vicinity of the rivet holes. It is of interest to record that he thinks that the low yield may probably have assisted failure by fatigue. This is a well authenticated case of failure carefully investigated by a recognized authority, and is certainly most instructive. It is hoped to refer to it later. The actual manner of the distribution of the stresses in the vicinity of the rivet holes is of considerable importance, and has been tackled by several investigators, notably Dr. Wolff. The design and technique of the riveting will always have a profound influence, and no doubt many of the failures in boiler plates might be rightly traced in that direction.

(To be continued)

Assuming that 10 per cent. of the total power represented by the Victoria Falls, Rhodesia, can be usefully developed, the water powers of that country are capable of generating about 220,000 electrical horse-power. Of this amount some 95,000 horse-power would come from the Victoria Falls and the following rapids at Kariba Gorge and Mapata, while the Sabi River system would supply about 91,000 horse-power.

Worth-While Information From Many Points

A bolt that has been lost may be replaced by a wood screw and a leather nut. This idea is especially useful on small-sized vehicles, ton wagons, baby cabs, and the like.

* * *

An American still holds the world's airplane altitude record with 28,900 ft., as recent rereading of the British claimant's instruments showed a revised height of only 27,000 feet.

* * *

A hoeing machine, invented by Otto F. Ullman of Severy, Kansas, operates several hoe-blades simultaneously. It does the work of three or four men armed with hand-hoes. Only one man operates the machine.

* * *

When a piece is held in position on an arbor by means of a nut and washer, it is usually necessary, in order to remove the piece, to take the nut entirely off. Where a number of pieces are to be handled, this requires considerable time. To avoid this time-wasting method a slotted collar may be used, making the nut and washer of such a size that the piece may be slipped over them without removing them from the stud.

* * *

Magnetized screwdrivers are useful for many classes of work, the carbon steel of which screwdrivers are made being capable of retaining considerable magnetism. A screwdriver which will retain a considerably stronger magnetism than an ordinary one, may be made from a round piece of tool steel, or preferably of tungsten steel, by simply grinding the end of a bar into the form of a very short screwdriver blade.

* * *

The use of a cold chisel by anyone inexperienced with it usually results in the hammer occasionally striking the hand instead of the chisel, with disastrous results. For the use of beginners, and possibly some of the older workmen who occasionally fail to hit the chisel directly on the head, it will be helpful to cut out a disk of old leather belting, making a hole of the proper size in the centre, and mount it on the end of the chisel to break the force of any misdirected blow.

* * *

Two large shipwrecking firms in England have been commissioned by the British Government to receive and distribute certain of the waste war materials imported from the Western fighting front. Scrap iron of low grade is melted into bars for the tin-plate industry. Steel bars of better quality are rolled into plates that are used in constructing trench shelters. Approximately 80 per cent. of the tin, terne, and black-plate mills of the kingdom are situated within 20 miles of the port at which the scrap is received from the continent.

* * *

"Flivver" airplanes that will carry two passengers and have a wing spread sufficiently narrow to make possible a landing on a country road are to be manufactured at the Maryland Pressed Steel Co.'s plant at Hagerstown, Md., according to reports. The first plane of this type was witnessed by the July 4th gathering at Towson and is the invention of an Italian. It was the idea of the War Department to use the planes in France, but after the signing of the armistice the inventor was induced to work on a peace plane.

* * *

A jackshaft or conveyor, if driven by a belt, may give a warning of its own stoppage by the use of an electric-bell wire with push button, and over it a piece of slat, held up by a spring. Place these so that if the belt comes off, part of its weight comes onto the slat, thus depressing the push button and closing the circuit. This may be used with either horizontal, vertical, or inclined belts, provided the surroundings permit the installation of wires and push-button support at suitable points. More than one bell may be wired up, each with its own circuit and its own push button beneath the slat, or several buttons may be connected through the signal lights to the same bell.

* * *

An electric-heating system which utilizes power that would otherwise go to waste has been installed in a school in a southern European city. The existing hot-water pipes and radiators are connected with a well-insulated water tank of 1,300-gal. capacity. In this reservoir electric resistances are built and at night are supplied with current which raises the water to well above the boiling point. The cost of the current is low because the water power used to produce it normally would go to waste. During the day the hot water is allowed to circulate through the radiators, its volume being sufficient to warm the rooms without using more current. The desired temperature is maintained by a thermostat.

* * *

At Portland, Oregon, a gas container 70 feet in diameter and 75 feet high, weighing 300 tons, was moved a distance of three miles. First, it was raised 15 feet and loaded on rollers. Then it was moved four blocks through the city streets and lowered 28 feet to a dock, whence it was moved upon a pair of barges. The barges were towed three miles to a shipbuilding plant, where the tank was unloaded and raised 26 feet, moved across newly-filled ground for a distance of 2,000 feet, crossing a railroad track and placed on its new foundation. It took 71 days to complete the work.

* * *

Shoe soles with metal coverings were made by Germans during the war—leather, cardboard, or wooden soles covered with aluminum or iron, not more than 0.01 mm. thick. The weight was the same, but they lost flexibility, became more solid and quite water-tight.

* * *

In concluding a paper to be read before the American Institute of Mining and Metallurgical Engineers, Messrs. P. D. Merica, R. G. Waltenberg, and H. Scott say that in the heat treatment of alloys of the type of duralumin the temperature of quenching should not be above that of the $CuAl_2$—aluminum eutectic, which is usually about 520 deg. Cent., but should be as near this as possible without danger of eutectic melting. The pieces should be held at this temperature from 10 to 20 min., and quenched preferably in boiling water. The hardening for most purposes may best be produced by aging for about five days at 100 deg. Cent. The hardening of duralumin during aging or tempering after quenching presents a very close analogy to that of steel, and the evidence in support of the theory is of the same nature and of approximately the same competence as that in support of the prevailing theory of the hardening of steel.

* * *

A simple device for improving the shearing strength of bolted joints in wooden structures has been brought out by Professor C. Forssell, of Stockholm. It takes the form of a corrugated washer, which is threaded on the bolt between the two pieces to be joined. The bolt is tightened against a pair of plain washers on the outside with sufficient pressure to force the corrugations into the wood. The strength of the joint is thus unaffected by the bolt hole, and depends on the friction between the two surfaces which are proportionate to the size of the washer and the depth of the corrugations. The strength of the joint is increased, according to Ingenioren, about twofold. The washers are known as "Bufo" washers, and made in various sizes, but all 1-16 in. thick, with corrugations about 9-32 in. high. In order to permit sinking into the wood, it is necessary to remove all knots at the joints to a depth of 3-16 inch. to 3-8 inch. The bolt is screwed up with spanners not less than 2 ft. to 2½ ft. long, and it is necessary to repeat the process after the first 48 hours and a further 72 hours.

WELDING AND CUTTING

Welding Jigs and How to Overcome Distortion

The Subject of Welding Jigs, and Various Methods for Overcoming Distortion as Presented by a Paper Read at a General Meeting of the British Acetylene and Welding Association

By C. S. MILNE

THE president, in opening the discussion, said:—

Mr. Milne is to be congratulated on the very thorough manner in which he has dealt with his subject.

This paper and his illustrations bear all the evidence of complete knowledge and careful preparation.

From begining to end he must have devoted a great deal of time and thought, taken a great deal of trouble and incurred a fair amount of expense in completing it. It is something out of the usual in these days to find a busy man who is prepared to do so much.

For all this we are grateful and trust he will feel sufficiently recompensed by our appreciation to-night and that which will no doubt follow from others when the paper is published.

The information he has given must surely be of great value to those concerned in the industry, and therefore I hope this paper will be widely circulated, because, as I am never tired of saying, the efficiency of the whole industry is more important that the super-efficiency of any one firm or system.

I think this idea is gradually sinking into the minds of those concerned in this industry. They should recognize it and give us all the encouragement and assistance we need.

I don't know that I can put forward from the practical point of view any useful criticism on Mr. Milne's statements. I will leave that to the experts. I dealt very faithfully with his matter in revising these proofs, and pointed out a number of small slips.

I mention this because Mr. Milne was grateful for having these trifling slips pointed out, and I am certain he will be equally grateful to anyone present who can point out any such slip on the practical side, because he is broad-minded enough to recognize that we are banded together in this association for the common object of advancing the industry and making all connected with it as efficient as may be.

Mr. Dixon said: I am sure that we are all very much indebted to Mr. Milne for his very valuable paper. It has been most interesting and we have learned a great deal from it.

There is one point, however, which I should like him to amplify, that is with reference to the statement that he considers it bad practice to weld and rivet the same joint. He does not qualify that in any way by saying whether he refers to all classes of metal whether under tension or compression. Take the case of welded seams that have been rivetted. It is well known that rivetted seams, no matter how well and carefully done, are not tight under external pressure unless the laps of the same are caulked thoroughly. Now, it has been a practice in a good many cases instead of calking, to adopt the system of welding the laps so as to effect a sealing. In the very valuable examples of modern welding which we have seen this evening the majority have been in connection with mines, and one, I think, in connection with trench mortar bombs. In these cases they we made principally, I believe, of steel plates. In the case of the mines, they are not subjected to tension or tensile pressure in actual work.

The only pressure which comes upon them is the pressure due to the depth under water in which they are placed, and the internal pressure is caused in both cases only when the fuse is started and disruption is required to give a violent explosion in order to cause destruction.

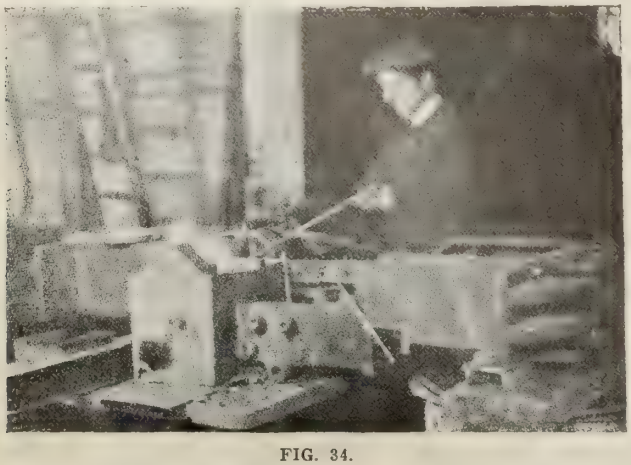

FIG. 34.

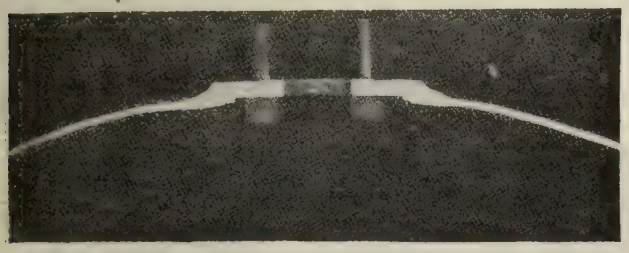
FIG. 36.

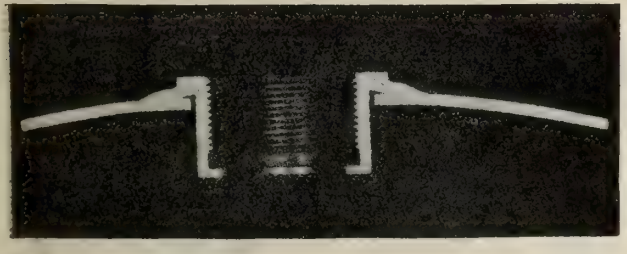
I suggest that in the case of steel vessels which are subject to internal pressure by means of steam or other ex-

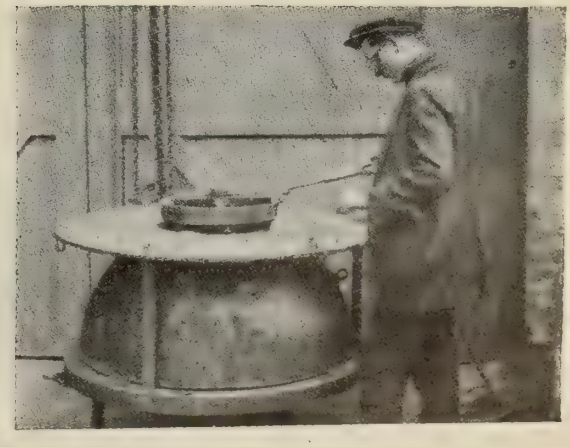
plosive gas, when we get a rupture in the plate, consequent upon sudden reduction of atmospheric pressure, a more violent disruption take place and a disastrous explosion occurs. In such a case as that a large number of engineers consider that when a steel plate is welded the weld should be covered by means of a butt strap and when such things as hemispherical ends are welded to a cylindrical vessel, that they should be reinforced by through stays.

In these circumstances I should like to ask Mr. Milne whether in his valuable experience he considers it absolutely safe and desirable practice that steel plates of ordinary commercial quality, say 26 to 30 tons per square inch, which are subjected to internal pressure by means of steam or other explosive gas, are absolutely safe without being reinforced in such a way as I have suggested?

Capt. Harley said: Although I speak with some diffidence as a member of







SOME INTERESTING EXAMPLES OF WELDING.

Mr. Milne's firm, it did occur to me, as one having had a very long experience in this class of work, that his remarks upon riveted joints might be subject to some elasticity. If you take the cover of a vessel which has to be sealed and you rivet or bolt that flange to resist the pressure of the fluid or gas against the cover, you would probably have to caulk also, but it might be preferable to seal the edges by welding.

The welding is useful on the edge for this purpose of sealing, but would not countered, but he has shown us the actual way he has solved them. I would like to ask just one question: Does he anticipate being able to go further into his machine-welding device or shall we have to wait for another war?

The president: I know Mr. Milne would like to have a few more pertinent questions. I was afraid when we started that we should have to adjourn the discussion to another meeting.

Mr. Thomson: This is the first time I have had the pleasure of meeting this interested in that particular industry and I would like Mr. Milne to let me know whether he has any experience in connection with the welding of the crowns of cylinders of internal combustion engines that have been fractured?

If a job of this description could be made successful by welding I daresay I could find him some work to do.

The president: I will now ask Mr. Milne to reply to the question which have been raised.

Mr. Milne, replying to Mr. Dixon's

FIG. 26.

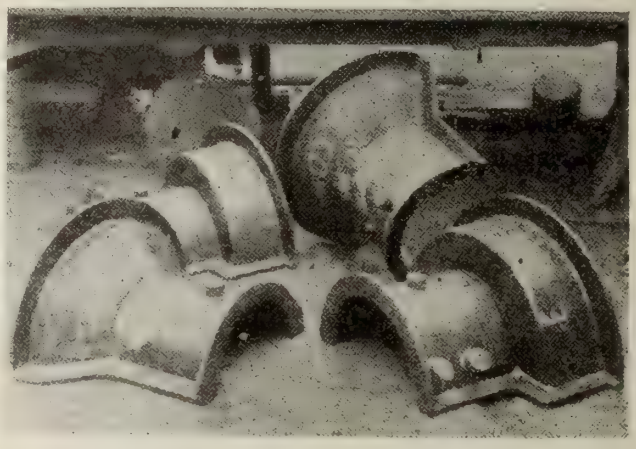


FIG. 27.

necessarily be any good against intense pressure on the area of the cover. In regard to the last speaker's remarks about mines, you must consider the question of disruption in relation to that of welding, because if your weld were to yield at the moment of destruction the mine would be absolutely useless. The hemispheres would simply come apart and would not have any retentive effect at all against the explosive charge.

You do not have longitudinal stays in mines. C. S. Milne & Co., Ltd., have made a great many mines which I do hope went off effectively, and I think we may say that the hemispherical welding, without the use of stays has been a success.

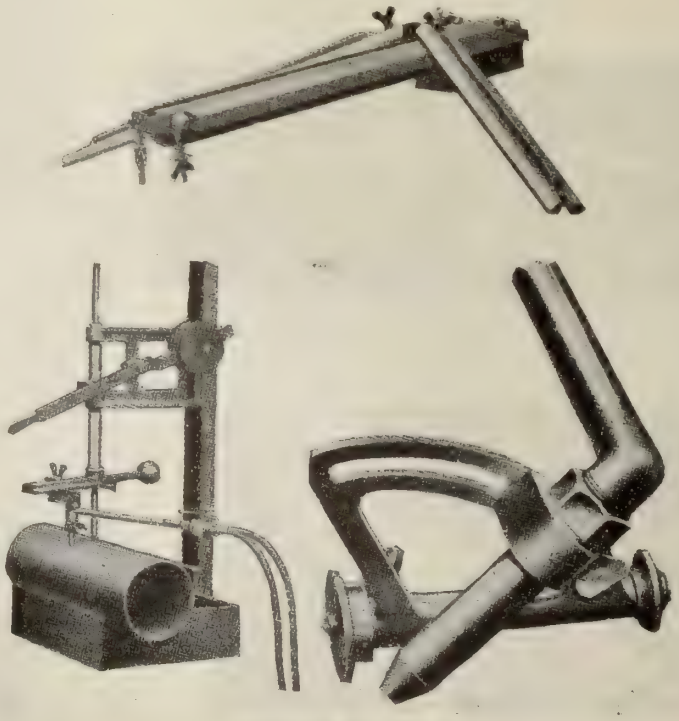
Mr. J. J. Gardner asked: In the case ipulation of the blowpipe by one of the workmen depicted by means of the lantern slides which illustrated the lecture, and asked for some particulars as to why Mr. Milne liked his welding on the work which had to stand tests which were beyond the ordinary?

Mr. Metcalfe enquired if Mr. Milne made any provision in the cutting machine, shown in Fig. 31, against the rubber tubes getting tangled?

Mr. Pickett said: Can Mr. Milne give us any information with reference to welding fractures in copper? This question particularly interests me and I should very much like to know whether Mr. Milne has any information on the subject.

Mr. Albert Hoddle said: I am sure we are all very grateful to Mr. Milne for the way in which he has dealt with the subject of his paper. He has not only described the difficulties he has en- association, and as comments have been invited, I should like to say that I failed to recognize among the many slides one that has dealt with the component parts of motors, or castings connected with internal combustion engines. We have to recognize now that motor transport is a very great power in the land and a great deal of acetylene welding has to be done with these various parts. I am query and also to Capt. Harley's remarks, said: My point was, if riveting is satisfactory, why weld? and if welding is good enough, why rivet? On the question of chambers that are in excessively high tension due to internal pressure, I think that you had much better stick to your riveting and say nothing about the welding.

To be Continued



FIGS. 28, 30, AND 32.

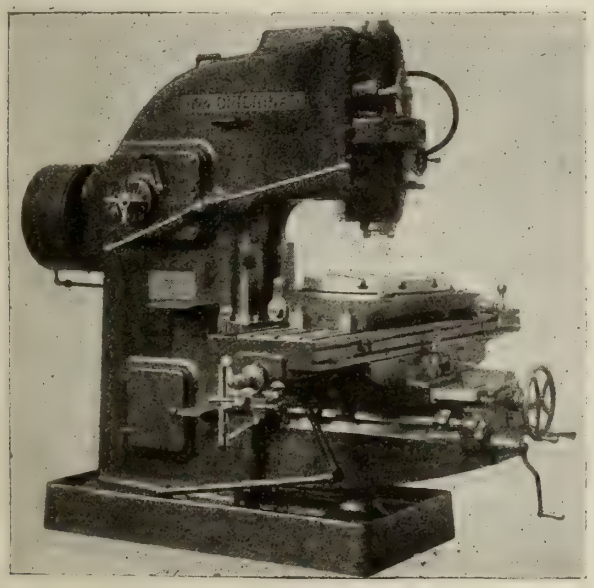
DEVELOPMENTS IN SHOP EQUIPMENT

No. 4 VERTICAL HIGH POWER MILLER

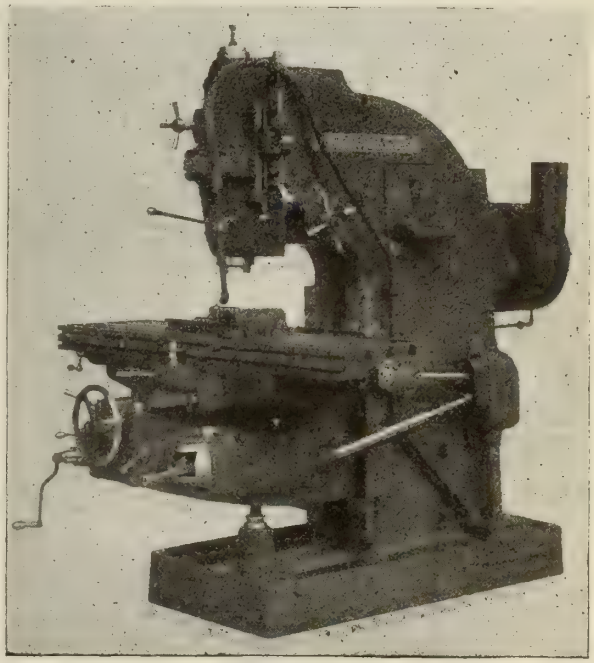
As a result of the success attained by the new No. 5 High Power Horizontal Type Cincinnati Milling Machine, the Cincinnati Milling Machine Company has placed on the market a heavy vertical machine of similar design, embodying the same features. This new machine is intended for extremely heavy work and it patterned after the No. 5 in all those elements which are common to both machines.

For die work, some classes of tool room work and many manufacturing operations, the vertical spindle milling machine has many obvious advantages over a machine of horizontal type. Chucking the work, in particular, is often simpler and the work is more accessible and very easily observed. Also, in combination with a rotary milling attachment the vertical spindle machine becomes a continuous miller.

The strains set up by the cutter in the vertical machine, particularly when using the large diameter face mills



BACK VIEW OF THE MACHINE.



GENERAL VIEW OF MACHINE FROM OPERATING SIDE.

for which this machine is designed, are just as severe as those which must be taken by the horizontal machine of the same horse power rating. However, all horizontal machines are provided with braces for tying the upper part of the machine carrying the cutter and the knee which carries the table and the work, together. There is no such provision on a vertical machine and the strains must be absorbed by the knee and column and those parts must therefore be made very strong and solid to take heavy cuts at high rates of feed. The illustrations will indicate that the column of this new machine has unusually great depth and width and the walls are thick and well ribbed.

The Knee

The knee is the other member which must absorb these same strains and also carry the entire load of the table, saddle, fixture and the work. This portion is well ribbed, and so designed as to allow ample thickness of walls. The openings are small and are placed as far as possible in the neutral sections. It is connected to the column by rectangular bearings with square gibs and narrow guides which together with the rigid construction of the knee itself provides ample strength for the maximum cuts and heaviest load this large machine is designed to carry.

The Saddle

The saddle is long and its extreme width provides an ample bearing for the table. Its bearings on the knee are again rectangular, square gibber and with a narrow guide which provides good sliding conditions even when the table is heavily loaded, and at the end of its travel. This square gibbing also enables the incorporation of a very effective clamp for securing the saddle to the knee. This clamp is, in fact, so effective that no special stops or other facilities are required for holding the saddle in position when heavy irregular cuts are being taken. The saddle details are shown on figure 2, which also illustrates the liberal proportion of the feed gearing, the connection of the power quick traverse transmission and also the connection for the drive for the circular milling attachment shown in the heading of this article. This circular attachment is also entirely new, designed of strength and general proportions to suit the machine. By using this arrangement the machine may be converted into a continuous miller, at the same time allowing the use of the table feed independent of the rotary feed, and also the use of the power quick traverse for both the machine

table movement and for rotating the attachment table, the operator being relieved of all hand adjustments.

The Table

The table of the machine is 19 in. wide, has a working surface 68 in. long, with three T-slots ¾ in. wide, providing ample clamping facilities. In order to resist as far as possible the warping effect of clamping bolts when holding the work for heavy cuts, the table has been made of unusual height, box section, and has a large number of ribs to give it added stiffness.

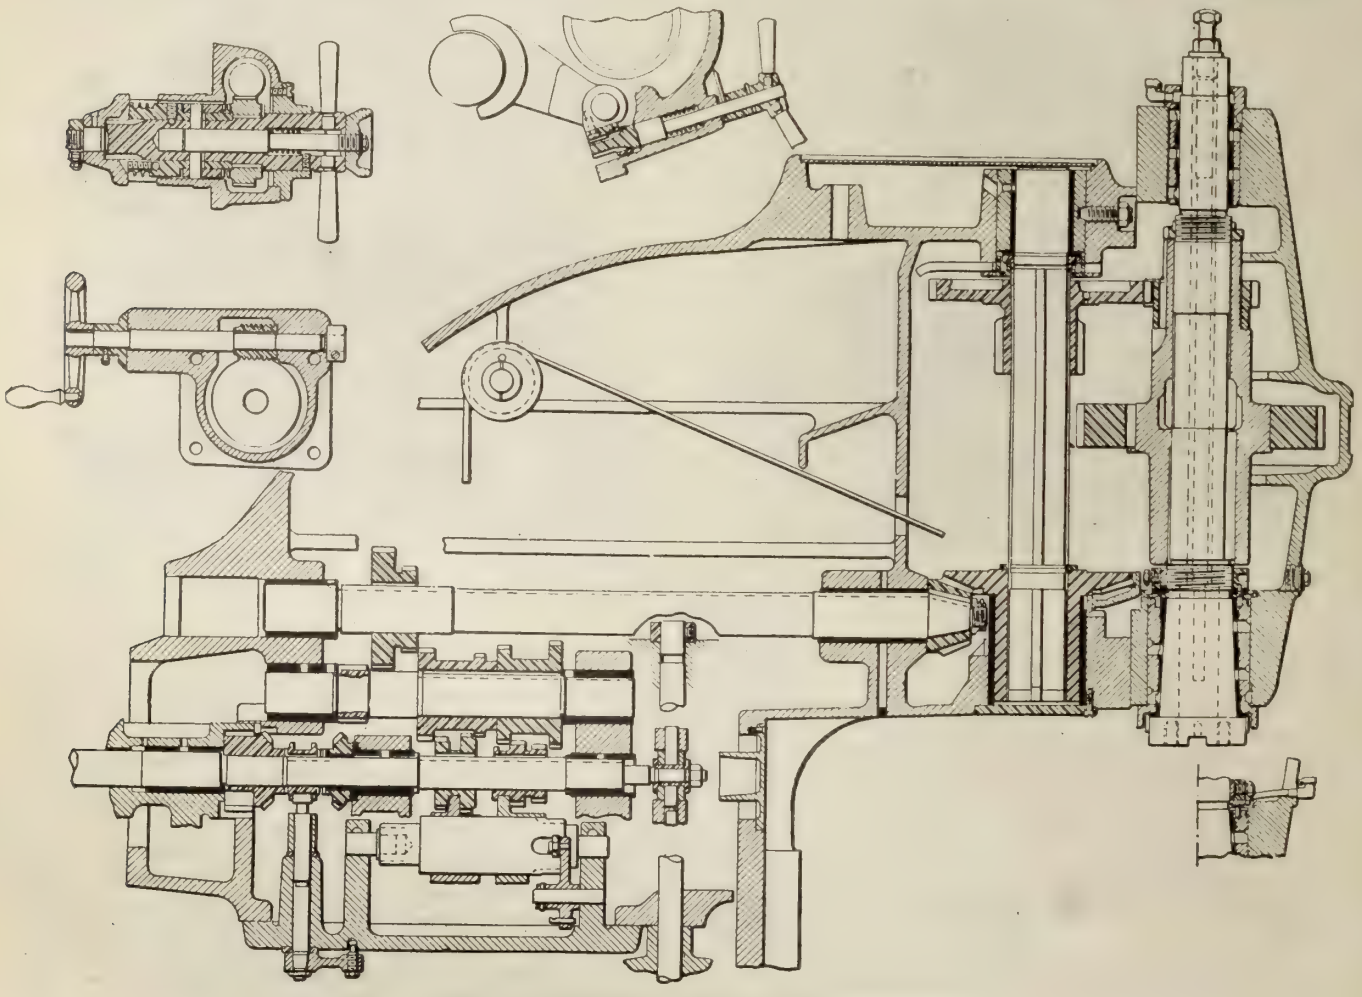
The main driving pulley runs on ball bearings and is mounted on a bracket fastened to the column which relieves the driving shaft of all belt pull. It drives the machine through a large powerful friction clutch which is operated by the main starting lever from either the front or rear of the machine. When the clutch is released to stop the machine an automatic brake is engaged and stops the spindle almost instantaneously. A belt guard conforming with the modern safety laws is also provided. The main driving pulley runs at a fast speed which allows the use of a high speed motor for either the belted or geared driving arrangements.

Speed Changing Mechanism

The speed changing mechanism is similar to that of the No. 5 machine except that the spindle and back gear shaft are turned to the vertical position. One of the novel features of this machine lies in the fact that this is accomplished by incorporating in the vertical machine the same large face gear and the same powerful mounting of the spindle as in the horizontal machine. The back gear shaft which is parellel with the spindle, and therefore, also in a vertical position, is driven through a pair of bevel gears, and back of those the entire drive is the same as on the horizontal machine. The speed changes are made through selective sliding gears. There are no tumblers in the machine. All shafts are hardened. This back gear shaft has four integral keys on which the back gears slide. This transfers the sliding feature from the spindle to the back gear shaft and eliminates the difficulty resulting from a construction that requires the spindle to slide through the gears. The gears on the back gear shaft may be selectively brought into mesh with the gears of the spindle and no matter which set of gears is engaged, when the spindle is adjusted vertically they may slide along with the head and retain their driving engagement at all positions of the head. The spindle itself has no gears on it but is surrounded by a sleeve, the lower end of which is slightly tapering and fits snugly on the spindle to which it is keyed at this point. This construction for all practical purposes makes the spindle and sleeve one piece, having the effect of merely enlarging the diameter of the spindle, and at the same time placing all strains due to driving on the sleeve to which the face gear for the slow speeds and secondary gear for the higher series of speeds are keyed. When the head is adjusted up and down these gears are carried with it and there is a connection between the head and the driving gears on the back gear shaft which moves them up and down to correspond.

The Spindle Head

The spindle head is square gibbed to the column and carries both bearings of the spindle in fixed positions in relation to each other for all positions of the head. The quick head adjustment may be made through the pilot wheel at the right side of the column, one turn of which moves the head 6 inches, the full adjustment. There is also a slow adjustment provided through a hand wheel (worm and worm wheel) which is brought into engagement



GENERAL SECTIONAL VIEW OF THE MECHANISM.

by means of a fine tooth clutch operated by a knob in front of the pilot wheel. There is a micrometer stop and also a micrometer dial provided. The details of the head are shown on figure 3.

The Feed Mechanism

The feed mechanism, similar to that of the No. 5, is placed at the side of the knee and the feed changes are made by a single lever operated from the front through a system of sliding wears. The changes may be made instantaneously from one feed to any other by merely shifting the position of this lever. Its location and the ease with which the feeds may be changed also makes the fast feed of 30 inches per minute available as a quick traverse for cross and vertical adjustments. The standard feed range is ¾ to 30 ins. A slower or faster rate may be furnished when desired.

The individual feed levers for table feed control, each of which starts, stops and reverses its corresponding feed, also at the same time indicate the direction of movement and these levers are duplicated at the rear of the machine so that the feeds can be controlled from a position behind the table when the size of the work makes this position desirable. The table feed lever has five positions controlling the starting, stopping and reversing of the table feed, and also the quick traverse of 100 ins. per minute for the longitudinal movement in both directions. The trip mechanism is arranged for intermittent feed, this feature being made available by setting the necessary dogs to suit the work and the intermittent feature may be used for feeding in either direction. This feature saves much time on work in which the cut is intermittent, the fast and slow feeds being controlled entirely by dogs, automatically bringing the quick traverse into action at all times except when the feed rate is being used. This is one of the outstanding features of this new machine and is a great time saver. One of the cycles of movement which is especially useful in the vertical machine is the continuous reciprocating cycle. The application of this cycle is as follows:—Assume 2 pieces of work on the table some distance apart and assume the cutter in the space between the 2 pieces. The operator starts the machine; immediately the table moves quick until one of the pieces has arrived at the cutter, when the dog trips to the feed rate, the work is fed under the cutter and then the table is reversed and is returned at the quick rate until the cutter arrives at the next piece, when a second dog trips to the feed rate and after this piece has been traversed the table is again reversed and a piece which the operator has in the meantime chucked in the other fixture, is again brought to the cutter and so on. This is continuous reciprocating milling, the operator chucking a piece in one fixture while the machine is milling the other, the entire operation of the machine being automatic. Another feature is that the table and cross feed can be used consecutively, being dog controlled. The design of the trip members is such that with the dog in the path of the trip plunger the power feed can be easily reversed and the table fed in the reverse direction, so that the work can be finished in a square or rectangular path in either direction.

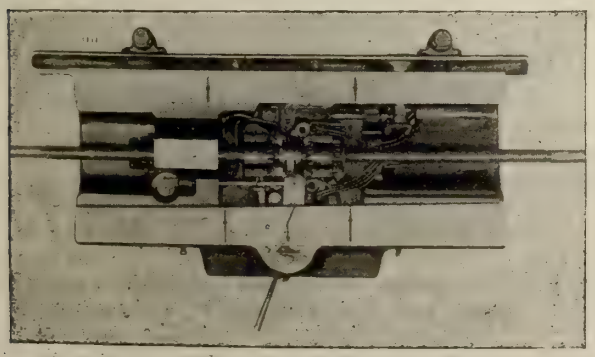


FIG. 3—PLAN VIEW OF THE SADDLE.

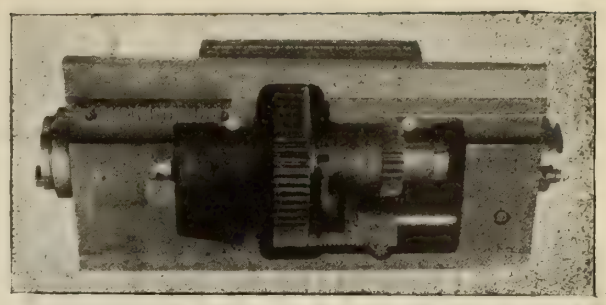

FIG. 2—DETAILED VIEW OF SPINDLE HEAD.

The Pump System

A centrifugal lubricant pump with a capacity of 11 gallons per minute is supplied as regular equipment for cooling the cutters. A geared pump placed in the pulley bracket provides automatic lubrication of all mechanism in the column, and several centralized oiling stations provide quick and convenient oiling facilities for the bearings in the knee, saddle and table. Another feature is that it is not necessary to set the table in a certain position for oiling the inside parts of the saddle and table and their bearings, as these parts may be oiled with the table in any position whatsoever.

Figs. 3 illustrates the spindle head detached and shows the two main gears and the gear shifting mechanism, as well as the method in which the gear assembly slides on the back gear shaft to allow for spindle head adjustment.

The remaining illustrations are self-explanatory.

A service of genuine worth is rendered to its patrons by one automobile manufacturing company. When it is reported to the central factory that a car has been lost or stolen, the factory history is consulted and the car's secret markings collected. In bulletin form these markings are then sent regularly to the company's dealers and garage men, who know that a thief always erases the engine mark but usually overlooks the number on some small, inconspicuous part. In this way the company has been able to recover hundreds of stolen cars in the last few years.

A claw hammer of the usual kind with a wood handle may be made very strong for heavy work, such as pulling very large nails. This can be done by sawing out an opening in the handle from the hammer head back past the centre of the handle an inch or two and inserting a strip of very narrow old steel buggy tire and securing in place by drilling small holes through both handle and buggy tire strip. The proper place for the holes is just back of the hammer head, one in the centre, and one just back of the centre an inch or two from the end of the buggy tire strip. Sometimes the drilling may be dispensed with by selecting a strip of buggy tire with bolt holes in the proper places.

The term shell shock has misled many persons to believe that it is due to the profound impression or shock produced on the nervous system by the detonations of high explosives. No doubt, there are cases of actual brain or nerve injury due to concussion of the air accompanying shell explosions, but these mechanical causes are a great deal less frequently responsible for war neuroses than the mental effects of general war strain. It is remarkable that these war neuroses, common as they are among privates and officers alike, are seldom found in men who have been actually wounded. Perhaps this seeming anomaly is due to the actual wound shock offsetting the mental impression affecting the controlling nerve-centre in such cases.

Tearing Down Tariffs

AT the gathering of the Liberal party at Ottawa a few days ago the matter of tariffs came in for some very strong talk. The broad statement was made that tariff should be taken entirely off some lines such as agricultural machinery, tractors, etc.

The trouble is that when people come together at times such as the Ottawa gathering, they are apt to talk in glaring generalities without getting down to real facts and facing all the conditions.

Taking the tariff off of any line and throwing a Canadian shop into competition with the world would mean, if there were to be any degree of fairness in the matter, that the Government should see to it that that shop has all the advantages that the competing manufacturers have. There should be the same ability to buy raw materials at the first cost, equality of carrying charges, etc. There are a large number of things to be considered, but in the heat of a convention called for the purpose of framing a platform they are generally overlooked.

The majority of the Canadian manufacturers are not of the Haman's gallows type of tariff makers. They are reasonable. They are not clamoring for tariff as a bonus for inefficiency. They have learned that it is possible for Canadian goods to be made good enough to enter the markets of the world.

But those who propose to bring into effect a tariff in Canada that would wipe out all protection and all tariff, regardless of the amount of revenue it would destroy in these days of high taxation, must think seriously of what they are about if they do not wish to strike at the root of much of Canadian industry.

What is needed, and what seems very hard to secure, is that there should be a scientific and careful study of the whole tariff field in a scientific and thorough manner. Political conventions have vague notions on tariff matters, for the simple reason that those who attend have not studied the matter in a big enough way.

A Strong Indictment

AT a time when the household preserving industry should be in full swing, the supply of the most important ingredient, sugar, has been ruthlessly suppressed, presumably by the large interests who can control the supply. The authority for this statement is Dr. R. J. McFall, the Cost of Living Commissioner. Without any attempt at equivocation, he states that sugar is being deliberately kept from the housewife in order to prevent her competing with the canning combine.

In support of this he shows that the amount of sugar being refined in Canada is more than sufficient for the needs of the country, and the imports are in excess of the exports. An advance takes place in Canada in spite of the fact that it remains stationary in New York.

It would seem that here is a clear case for Governmental action. With the amount of discontent and unrest apparent throughout the country, conditions such as are here disclosed are nothing less than criminal. People naturally think if these things are true of one type of big business they are true of all.

Will those in power be able to take their eyes off the political situation long enough to look into a condition which affects so vitally the pockets of the voters?

THE latest horror to be perpetrated on a long suffering public is an actors' strike in New York. However, the tired business man can pluck up courage. The chorus girl is sticking to the job.

* * *

THE Cost of Living Commissioner says that the sugar trust is boosting prices to help the canners' combine. We trust the people will combine to can both the canners and the sugar trusters.

* * *

That the state may have a sufficient number of tractor drivers to cultivate the maximum amount of land, and so increase the food supply, the California State Board of Education has been conducting emergency classes in tractor operation in the rural districts. The course given lasts three weeks and costs only $2.50. The first week, the students are taught the theory and principle of gas engines; the second week, the assembling and disassembling of tractors, their operation and repair, and the third week they drive tractors in the field.

* * *

It would seem that the phenomenon of growing old has really nothing to do with the number of years that an individual has lived, but depends principally on the extent to which he has conserved his recuperative powers. The human body wears out in two ways, i.e., either by long-continued use or by long-continued disuse. In the former case it is like bending a wire back and forth in one place until it breaks, and in the second it is the atrophy of organs or functions through disuse. The only way to stave off old age is to eliminate all forms of abuse and live as Nature intended us to live.

Advice to the Draftsman; Get Out of it

By Thernaldus

THE draftsman's life must truly be a hard one if all is true that has appeared in two previous numbers of CANADIAN MACHINERY and unfortunately, it is. From the writer's point of view the unsatisfactory state of affairs existing to-day is due to several causes.

First the draftsman himself. "The attractive surroundings and cleanliness of the work itself," undoubtedly appeal to many youths and to their parents. This is responsible, perhaps, for the number of so-called draftsmen seen to-day pushing a pencil who might better be counter-hopping in a dry goods store or behind the wicket in a bank. The same remark also applies to the product turned out by engineering schools in vast numbers, with sheepskins enabling them to design everything from Quebec bridges to cast iron bath tubs. For among them too many are found who are utterly unsuited for any engineering profession. This state of affairs is due perhaps to the glamor of the engineering profession, but more likely to the idea unfortunately mistaken that the engineer's stipend is of fabulous proportions.

However, if a man is not suited mentally for mechanical pursuits he might better stay out of them and get into something more to his capabilities, leaving the field open to those of the proper talents, to their better advantage.

The draftsman himself is also at fault through his mental inertia or laziness, call it what you will. The drafting room to a man of ambition and who is willing to work is but a step to something better. Take a look around any drafting room and you will find very few men who have reached middle age still bending over the board with tee square and set square. Where they go has puzzled the writer for some time, but an explanation might be found in the fact that the earnest ones desiring self improvement usually reach the designing engineer's office or some other sphere where their capabilities have better scope for their display, while the inefficient ones drop out of sight and are found in other occupations.

Not only is the draftsman himself at fault, but his employers are not altogether blameless. "One of Us" says it takes an average of four years to make an average draftsmen. This is all too true, and when the four years are up his knowledge is usually very limited and confined to whatever he may have been working on most of the time. It should be recognized that the apprentice (we may call him that though not articled) draftsman is entitled to a reasonable amount of educational opportunity aside from that which comes to him through his particular work. "One of Us" lays stress on shop training and this point can only be emphasized in the strongest of terms, for a draftsmen without shop knowledge is as useless as a doctor without a knowledge of anatomy. There is another side of the question of education which should be dealt with equally with the practical, however, and by this I mean the theoretical side of whatever branch of engineering is applicable.

It goes without saying that a mechanical draftsmen should have a good knowledge of machine design in all its parts, should know the principles of mechanics and their application, and should have a sound knowledge of materials and their strength. The electrical draftsman is in a somewhat similar position but his need for theory is even greater. In some cases his knowledge must approach that of an engineer. The structual draftsman, too, if he does not wish to remain a detailer on that everlastingly monotonous job of structural detailing, must have a knowledge of the theory of framed structures.

Where will the apprentice draftsman gain this specialized knowledge. Through his superiors? Yes, if they are willing as they usually are, and if the boss is acquiescent. Through home study? Perhaps, but it is a lonely job. Through technical schools? Yes, by all means, and it should be the employer's part to give a bit of encouragement and incentive.

The actual production of a pretty drawing is not so important. The neatest letterer in the room is usually given the job of lettering shop signs, etc. More to point though is an understanding of the principles of projection and the construction of a neat accurate drawing. How many draftsmen know whether they are drawing in the first or third positions?

The argument is often heard in the drafting room as to whether the college graduate or the practical man from the ranks is the better man and the discussion at times becomes quite bitter. The inconclusive nature of these debates is a guide to the equal value of both and the proper training for the draftsman, or, the engineer whether from college or from the practical side of the fence will be found in a combination of both theory and practice.

For the mechanic, the drafting room offers a means of acquiring the elements of engineering practice and this supplemented by his own efforts and study should make him a REAL engineer.

The engineering graduate fresh from the halls of learning has to, or should, reverse the process and go first to the shop, then the drafting room and from thence where he lists.

For the youth ambitious to become a draftsman the shop training as proposed by "Engineer," in one of the former rhapsodies on this subject, is absolutely essential and after he has entered the realm of blue print and tracing cloth his education should not stop, but change, and should smack more of the theoretical, gained by study at home, night school or otherwise.

The three elements, practical knowledge, theory and draftsmanship, should go together much as capital, labor and brains; all three necessary to the achievement of success and all as necessary as are the three legs of a milk stool, n.b., this simile is not mine.

After all this suppose we have a finished draftsman or really a designing engineer and he comes for advice regarding the remuneration offered for his really worth-while efforts. If he asked the writer's advice he would say: "Get out of it."

MARKET DEVELOPMENTS

There is a Fair Amount of Business Moving

While Not so Active as Previous Week, Machine Tool Trade Shows Steady Business—Steel Warehousemen Report Good Business

THE general feeling among machine tool dealers and steel warehousemen is that business is satisfactory, though not quite as lively as during the previous week. There is some hesitancy still being shown by machine tool purchasers regarding the probabilities of labor troubles interfering with business later on. While there are plenty of machinists available now, the fact that in many places molders are still on strike makes it impossible for the machine shops to be fully engaged.

There have been no changes in steel prices since last week. That a change must come before long, and that when it does it will be upward, is the opinion of those interested in these lines. There is still a difference of opinion as to the probabilities of an advance in plate prices, but the fact that mills are operating at 75 per cent. capacity and will not promise delivery before last quarter would seem to preclude the idea of a drop in prices.

Pig iron still shows advances. Many furnaces are now booked up for the rest of the year and show no anxiety to book business for next year. What bookings have been made for first quarter have been at an advance of from $1 to $2 a ton over present prices.

In the scrap market the scarcity of steel scrap is still the feature, and prices for heavy melting continue to advance. Dealers are holding on to what they have for better prices, and sales at $23 per ton have been reported. Cast scrap has reached a point in some districts where furnace men are buying low grade pig as being cheaper than scrap.

BUYING OF MACHINE TOOLS KEEPS STEADY

TORONTO.—While business in the machine-tool trade is fairly active, the still unsettled conditions of the labor market is having its effect on buyers. One dealer reports having placed twelve machines last week, part new and part second-hand. The general feeling is that there is nothing to complain about in this line.

Considerable interest is being taken by dealers in the buying now going on at Walkerville, at the plant of the Canadian Products. While the proximity to Detroit is somewhat of a handicap, the Canadian dealers are getting some of the business. Some lines of course must be purchased through Canadian houses where they have the sole rights of the territory.

The steel market is at the moment practically stationary, but as this is not a natural condition, a movement in prices is expected shortly. That this movement is to be an upward one is pretty generally believed.

One feature of the situation is that plate mills now refuse to promise delivery on orders before the last quarter. A few weeks ago delivery could be obtained in two days, if required. The mills are now operating about 75 per cent. capacity, which is high. This would seem to be against the idea that plate prices would drop, although that is still being entertained by some well-informed men. There is a good quantity of plate still being brought into Canada to fill existing contracts in the shipbuilding and marine engineering lines.

Warehousemen report very good business, which is keeping their stock turning over. The railways are buying freely. August is generally looked on as a dull month so the situation may be called very satisfactory.

There is practically no change in the scrap situation since last week, the scarcity of heavy melting steel still being apparent.

AUTOMOBILE INDUSTRY IS RESPONSIBLE FOR MUCH BUYING

(Special to Canadian Machinery)

NEW YORK, Aug. 11.—The volume of machine-tool buying is steadily increasing, but a large proportion of the orders and inquiries continue to come from the Central West and particularly from the automobile industry.

The White Company, of Cleveland, manufacturers of trucks and passenger automobiles, has made inquiry for 250 to 300 tools for an addition to its plant and other large buying by auto makers is in prospect, while the day-to-day business in the Detroit territory makes up a very satisfactory aggregate for many tool builders.

The Hudson Motor Co., Detroit, will build a large plant at Detroit for the manufacture of Essex cars and perhaps $1,000,000 worth of equipment will be required, while buildings will involve about an equal expenditure.

Dodge Brothers have purchased a large tract of land near Detroit for new manufacturing capacity, and it is rumored that this concern may erect its own steel plant and sheet mills. Ground will be broken soon at Marysville, Mich. near Port Huron, for the new plant of the Wills-Lee Company. This will be one of the largest automobile plants in the country and many millions of dol

lars will be invested. The Canadian branch of the company will be located on land below Sarnia, Ont., which was formerly a part of the Indian Reservation.

One of the largest projects in the shipbuilding field announced since the end of the war is a $5,000,000 ship repair plant to be built near Havana, Cuba, by the Cuban Government. Monks & Johnson, Boston, Mass., contractors and engineers, who laid out the Alameda, Calif., plant of the Bethlehem Shipbuilding Corporation, and who have done much other important work for the Bethlehem interests, have received the construction contract. Equipment for plate shop, forge, machine shop, etc., will be purchased in the United States.

A maker of grinding machines and boring mills has advanced prices 5 per cent., but no further price advances are noted, other than those reported a week ago. Prices are firm, however, and there is practically no tendency among sellers to make concessions. The Standard Oil Company of New Jersey early in the year got quotations on about 75 machines for shipment to the Roumanian oil fields, but postponed buying, presumably on account of high prices. It is quite certain that the company now will pay much more, the list having been revived, as few sellers need business as badly now as when the list first came out, and the temptation to cut prices will not be so strong.

POINTS IN WEEK'S MARKETING NOTES

Steel plate mills are operating at 75 per cent. capacity and will not promise delivery before last quarter.

—

Machine-tool business is giving dealers satisfaction. Some big buying just now at Walkerville.

—

The steel output for the month of July was equal to 75 per cent. capacity of mills.

—

Scarcity of steel making grades still feature the scrap market. Cast scrap price in some cases up to that of pig iron.

—

Large quantity of ship and boiler plate still being imported into Canada to fill contracts.

STEEL OUTPUT FOR JULY WAS 73 PER CENT. OF CAPACITY

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., Aug. 14.—The volume of orders flowing to the steel mills keeps up very well, easily exceeding the current production, but an element of uncertainty has been injected into the situation, in that some of the buying may be prompted by fear that mills will have difficulty in making deliveries later in the year, either through their having too much business or through there being strikes. The steel producers think it highly improbable that the efforts of the American Federation of Labor, in the direction of having a general strike in the steel industry, will lead to anything, but in this matter it is not a question of what the producers think, but of what the buyers have in their minds. Strikes as affecting steel production, moreover, are not all in the future by way of probabilities or improbabilities, for the strikes of railroad shopmen have curtailed pig iron and steel production materially in the past ten days, considerable parts of the South Works and Gary Works in the Chicago district having been thrown idle through lack of transportation facilities, as well as practically the entire Newburgh works, Cleveland. The three plants mentioned are all controlled by the Steel Corporation. On the whole, steel mill labor itself appear sto be contented and to realize that it is well treated. The Steel Corporation in particular asserts that its men are well satisfied with their treatment, and the Steel Corporation takes great pains to ascertain the exact facts in this matter. Two incidents may be mentioned. The Leechburg and Vandergrift works, near Pittsburgh, of the corporation's sheet and tin plate subsidiary, employ about 2,000 men, and recently a mass meeting of these men gave an enthusiastic viva voce vote to a set of resolutions to the effect that they intended to keep at work "under present conditions" and that "we resent any interference by any union, outsiders, or paid agitators." Another incident is that at two independent tin plate plants the men asked the management to give them, not the Amalgamated Association, the union scale, but the open shop scale of the Steel Corporation's tin plate plants.

Steel Prices

The whole country has been much wrought up lately over the high cost of living and deep interest is taken in the efforts being made by all branches of the Government to bring it down by all methods available, including the punishment of profiteers. All price advances must prove very unpopular. Hitherto there have been divided counsels in the steel trade as to the propriety of advancing prices at this time, with the Steel Corporation and some of the independents positively opposed to there being any advances. In view of the state of popular feeling it is likely that the minority, which has been talking higher prices, will change its attitude.

In the pig iron market several price advances have been announced. Alabama furnaces state that they are back to the March 21 price of $26.75 on No. 2 foundry iron, which would put them in an impossible position as to sales in much of their territory when various northern furnaces, with much smaller freights, are still at $26.75, furnace. Chicago district furnaces are reported to have advanced their prices $2 a ton, and two Cleveland furnace interests report having made an advance of 50 cents. The Pittsburgh market is merely firm at the old price. The price advances are probably simply "on paper," the furnaces making them being sold up for a time. If 55 per cent. of the merchant furnace capacity of the country can advance prices without any of the idle 45 per cent. coming into blast then there is something possible that has never occurred before in the history of the industry. Usually the market is rather wobbly as idle furnaces come into blast, because they are not punctilious as to selling prices when they are accumulating a backlog of orders upon which to blow in.

Steel Production

The monthly report of the American Iron and Steel Institute shows that in July 2,508,176 gross tons of steel ingots were produced by 80 companies, which in 1918 made 84.03 per cent. of the country's total output of steel ingots. This means that in July the industry as a whole produced at the rate of about 35,700,000 tons per annum, or at 73 per cent. of capacity, taking the latter at 49,000,000 tons. This compares with rates of 67 per cent. in June, 54 per cent. in May, and 65 per cent. in April. Production has been increasing almost as rapidly as formerly it was decreasing, the low point, about 50 per cent., having been struck at the middle of May. In view of the dearth of orders for rails, plates and structural shapes it does not seem probable that the present rate of steel production can be greatly exceeded in the near future. Some departments, particularly the lap weld departments of the pipe mills, are oversold, but that does not help the departments that are short of orders.

Steel Corporation Tonnage

The Steel Corporation reports 5,578,661 tons of unfilled obligations on books at the end of July, indicating a gain of 685,806 tons during July, against 610,545 tons gain during June, and losses averaging over 600,000 tons a month in the six months preceding June. The corporation's shipments in July may be estimated at 74 per cent. of capacity, and as the increase in unfilled obligations represented about 63 per cent. of capacity the total tonnage entered in the month appears to have been about

127 per cent. of capacity, against about 117 per cent. in June and only about 20 per cent. in May. The figures, it must be remembered, include contract obligations, and thus give little suggestion as to shipping orders, which include specifications against contracts. The monthly tonnage reports indicated extremely light business during the six months preceding June, but the shipments were fairly good, being chiefly against specifications on contracts entered long before.

Exports

February marked the low point in iron and steel exports from the United States, 234,793 gross tons. Afterwards there was continuous improvement, June showing 544,580 tons, the largest amount for a month since December, 1917. Since about the end of June export demand has not shown distinct signs of increasing, and in some respects it has fallen off a trifle, though the latest reports suggest a revival. On the whole, however, it is probably not out of line to take it that the June exports are a fair guide to what may be expected in the matter of exports for some time to come, and general comparisons may therefore be indulged in. First, it should be noted that the iron and steel exports as reported by Washington include scrap, pig iron, unfinished steel, the various rolled products, and such manufactured goods as cast and wrought pipe, wire and nails, nuts and bolts, etc., as well as some castings. Accordingly, while comparisons can be made between months and years, comparison cannot be made between the total exports and the total production or the capacity. Eliminating pig iron, wrought iron and castings, the steel exports are left and can be compared with steel production and capacity. The June exports of steel represented a rate just a trifle under 6,000 000 gross tons on the basis of finished rolled steel, the productive capacity in which is about 37,000,000 tons a year, so that the exports of steel represented 16 per cent. of the capacity. Production in June was at about 67 per cent. of capacity and thus the exports represented about 24 per cent. of the production. In 1912, the best calendar year for steel exports before the war, the exports amounted to about 2,400,000 tons, and that was about 10 per cent. of the production. There are two ways of looking at most things. One may say that steel exports now are two and one-half times the best exports before the war. One may also say that while the present capacity of 37,000,000 tons is 14,000,000 tons greater than the production of 1912, the exports have increased by only 3,600,000 tons, and as there is no evidence that they are going to be much larger, it is more readily seen how idle was the talk during the war that afterwards the export demand would take care of the increase in capacity produced by the war.

MALLEABLE SELLING HIGHER

Advices from almost all centres show further advances in pig iron prices. Furnace capacity for 1919 is fully booked up. Malleable iron for first half brings higher price. Following are reports from U. S. points:

Chicago.—Foundry interests are evidently seeking to get as much iron as possible before prices advance again. 1919 production of furnaces will all be booked up before the end of this month at present rates of selling. Iron for 1920 is quoted at $2 over present prices.

Boston.—Sales through New England dealers approximate for the past week 10,000 tons. Prices have fluctuated, in some cases stiffening, concession being given in others. The general trend is towards further stiffening, with enquiry good. Some sales for 1920 have taken place, but the price has not been given out.

New York.—Enquiries are in excess of capacity in this district. A large tonnage for export could not be quoted on owing to lack of iron. For 1920 first half delivery, about 40,000 tons are asked for, but few furnace interests are willing to quote on next year delivery, feeling the labor market is too uncertain.

Pittsburgh.—The tendency of consumers is to cover themselves for their future requirements before prices get any higher. Steel making grades have been in demand, although steel makers are not busy. A quantity of low phosphorus iron was bought for $39 to $40 from a valley producer, while a sale of 3,000 tons of basic at $25.75 is reported.

Buffalo.—Furnaces are booked up in most cases for this year's delivery, and at least two are out of the market. Some 1920 tonnage has been sold, the prices reported being malleable $29; No. 2 foundry $28; No. 2X foundry $29, and gray forge $27.50.

Cleveland.—There have been good sales of round tonnages during the past week, due mostly to the talk of impending higher prices, consumers being anxious to get covered. Enquiry for 1920 is fairly brisk, but sales are few. Furnace stocks have been reduced more in the past week than in any preceding week this year.

Cincinnati.—There has been little business done here although prices are favorable, last quarter delivery being quoted at $26.75 Birmingham for 1.75 to 2.25 per cent. silicon. First half enquiry for foundry iron is coming out, but no sales are reported so far.

St. Louis.—Brisk business involving good sized tonnages has been the feature of the market here this week. Consumers who had covered on estimated business find it necessary to secure more material on extra orders. Sales are ahead of production, and it will be necessary to light up some idle stacks.

Birmingham.—Sales for third and fourth quarter are being made, and the market is strengthening. Several furnaces have been put in blast and others are expected to follow shortly. The increase of prices in other districts has had a good effect on the local market.

HEAVY MELTINGS STILL SCARCE

The scrap market shows great strength in both iron and steel scrap. Heavy melting and re-rolling were strong and in some cases cast scrap approaches the price of pig iron.

Philadelphia.—A large tonnage of heavy melting steel has been sold here for Pittsburgh shipment at $23 delivered. Sales generally are light, but prices are advancing on account of activity in other centres. All grades of scrap are scarce.

Boston.—An unusual feature was the sale of a small tonnage for fourth quarter delivery, pointing to the fact that consumers expect higher prices. This lot was sold at $28 delivered, and was of No. 1 machinery grade. Other lots of the same grade brought $26.50 delivered.

New York.—Borings and turnings have advanced slightly in response to a better demand. Sales of heavy melting at $22 are reported, but it is thought only small quantities have been bought at this figure by Pittsburgh users. Heavy melting is quoted $16 to $16.50 f.o.b. New York.

Buffalo.—Dealers are very active and prices firm. No. 1 machinery cast is quoted at $24.50 to $25.50 and No. 1 railroad wrought at $23 to $23.50. Heavy melting is quoted in the local market at $20.

Pittsburgh.—Consumers having covered their requirements for the present, the sales have quieted down somewhat, although prices remain firm. Heavy melting has sold at $22.50 and $23 is being asked. Railroad scrap is bringing higher prices for all grades, iron axles being quoted at $31. Low phosphorus has brought $25.

Cleveland.—Although consumers are not buying much the dealers are keeping the market strong. Prices have advanced in almost all grades. A round tonnage of heavy melting has been sold at $23.

Chicago.—A general advance on all grades of $1, and in some cases more, are the conditions here. Rerolling rails have shown a jump of $3 per ton, a small lot having been sold at $33. Railroad offerings are scarce. No. 1 cast, which sold above the pig iron price, is holding firm.

St. Louis.—The scarcity of scrap and the higher prices prevailing are causing consumers to look for low grade pig iron in preference to paying $28 for scrap. Scrap dealers are holding all grades and very little is offering either from railroads or country.

Birmingham.—The market is still behind, but a better spirit is apparent. Dealers have made some small sales. Quotations on heavy melting are around $15 to $16 but it is being held for $20.

Is Your Heating Plant Ready for the Winter?

While the Weather is Warm is the Time to Prepare for the Cold Time Coming—Cold Rooms in a Factory Are a Cause of Dissatisfaction to All Concerned

By T. H. FENNER, Associate Editor

IN that locality which is popularly supposed to be paved with good intentions, we are led to believe that no trouble is ever experienced with the heating arrangements. It is also an attribute af fallible human nature that once the immediate incentive of the said paving material has disappeared, action is delayed in favor of some more pressing need, till the recurring season brings along the old troubles, and a crop of vain regrets. All of which is merely a way of saying that to avoid six months of misery in the winter, a few days or weeks should be devoted in the summer to a thorough examination of the heating arrangements.

There are few things that lead to more lost time and bitter recriminations than the failure of the heating system to properly function at the required time. Workmen coming in to a cold room first thing in the morning are usually disgruntled for the remainder of the day, and are prone to stand around the shop, with their hands in their pockets, calling down anathema on the engineering department, rather than attempt to forget the temperature by an assiduous attention to the job in hand. In many cases they are not to be blamed, for a man who is engaged on monotonous repetition work, which entails but little bodily activity, is usually supersensitive to uncomfortable shop conditions. Furthermore, the plant superintendent, who has to sit in an office where the temperature is around 50 degrees, is not disposed to kindly feelings towards his chief engineer. The latter may not be entirely to blame, as oftentimes lack of sufficient or competent help has caused him to delay the necessary overhauling until an unusually early cold snap brings down trouble on his prematurely gray head.

A winter season such as we had in Canada in 1918-19 did not strain the capacity of the heating plant over-much, and the early spring, followed by the gloriously warm summer, was likely to dispel all thoughts of heating systems from the minds of the engineering staff, but there have been some chilly mornings and evenings lately which serve as a sharp reminder that our summers are short. If not already done now is the time for a sharp and systematic campaign, started at the exhaust line and carried through the factory.

The Right Time To Do It

The proper time to overhaul the heating system is the early summer, just as soon as one can feel that there is no chance of the system being required again that season. All its most obvious needs are, or should be, fresh in the mind then, and the unpleasant remarks caused by them still rankling in the breast. That main reducing valve, for instance, that requires a new diaphragm, the leaky joints in awkward corners of the basement, the vacuum valves which have ceased to justify their existence, and the countless other small things that have had to be neglected for the time being. Small things in themselves, but what a cause of misery in the aggregate.

Perhaps there has been no lack of heat in the factory, but the heat has only been maintained by the expenditure of a totally disproportionate amount of coal or else there has been both a lack of heat in certain sections, as well as a large coal bill. In the small and compactly arranged factory it may not have been very bad, but in the plant that covers a large area of ground, with the heating done from a central plant, the waste may be enormous.

Two Points to be Considered

There are two things to be taken into account. The heating system itself and the state of the buildings. There is little use in having a perfect heating system if there are ½-inch openings around window frames, door jambs, pipe entrances to buildings. The chief engineer should send his foreman bricklayer or painter or go himself if possible, and make a systematic inspection of the buildings, taking careful notes of all places where the cold winds can find entrance, and then take effectual steps to stop them. A little spring yarn caulked tightly into the spaces between window frame and brick work will work wonders in the way of comfort and saving of fuel. Where roofs are built with lanterns take a good look at the joint of roof and lantern, and see that there is no open space under the flashing, and that the flashing itself is in good repair. Count up the broken panes of glass and order the required quantity immediately so that it can be all replaced before the summer is over. There will be quite enough work to be done on building exteriors to keep a man or two busily engaged all summer, and there is no one more vitally interested in having this work done than the chief engineer. Every bit of cold air that enters a building by unauthorized inlets has to be heated up, and it all requires some of his dearly bought b.t.u.'s. Furthermore, a building that is reasonably tight will retain the heat for the better part of the night, when the main engines are stopped, and makes less demands on the live steam.

Coming to the heating plant itself, there is ample scope for useful work to be done. In a large factory there are miles of coils, thousands of feet of main feeders, risers and returns, and hundreds of steam and thermostatic valves, outside of the engine room altogether. The majority of plants using exhaust steam for heating are equipped with a vacuum return system, the returns being delivered to the feed water heater, and thence to the boiler. Where feed water has to be paid for, the more water that is reclaimed from the heating system the less has to be paid for. But it must be free from oil, and it is also necessary to have the oil extracted from the exhaust before it enters the steam heating system, otherwise it will coat the coils and form an excellent non-conductor. Therefore, the oil extractor on the main exhaust line should be thoroughly cleaned, and the trap or other drainage arrangements examined and put in good shape. The vacuum pump should next be overhauled, both steam and water ends, and rods turned up if necessary. The suction and discharge valve plates should be taken out, and if the valve seats are worn unevenly, they can be put on the shaper and faced up. Failing this, they should be faced up with a surface board and file and scraper. Overhaul the valve springs and valves, pack the plunger, and see that the pump barrel liner is not worn in the middle. If it is have it bored out. Once the pump is as perfect as possible you are in a position to start testing out your system. The usual arrangement of piping is a main carried from power house to factory basement, and individual branches carried to different sections of the building. The return branches are brought back to a return main, which is connected to the suction of the vacuum pump. The function of the vacuum pump is two-fold. It has to deliver the condensation from the returns to the feed heater, and also maintain a difference of pressure between the main exhaust and the return system, to ensure a circulation of steam through all the coils. If the pump is not doing its duty, there will be an increase of back pressure on the engine, and the heating system will be filled with water, the result being more fuel consumed, and a cold factory, while the heat that should be going into the building will be carried up the atmospheric exhaust to the open air. If there are leaks in the system anywhere the pump will be drawing air into the returns instead of maintaining a vacuum. Air leaks should be eliminated as far as practicable. Now shut off every branch valve, both steam and return, leaving only the length of the main return open

Continued on page 196

IS YOUR HEATING PLANT READY?

(Continued from page 193)

to the pump. Better still blank off the return branches in case there may be leaky valves on the branch where it joins the main. Blank off the water connection to the small condenser on the suction pipe and start the pump. You should get a vacuum immediately, and if your pump is in good shape you will be able to drain from 20 to 24 inches on the gauge. Now stop the pump, and if the length you are testing is tight, the vacuum will be maintained for a considerable time, say 10 to 15 minutes. If it disappears in three or four minutes there is a leak, which must be stopped. Now take the blank flange from one branch and connect it to the return main. This branch may carry four or more coils. Blank these coils off at the steam end, one at a time, and take the thermostatic valve out of the return end, and get the vacuum again. If it does not hold, take a candle, keeping the pump running, and try the flame at every joint till the leak is discovered. Try every coil in this way, till you are morally certain that your return system is airtight.

Then comes the steam side. You can test this out by taking out the thermostatic valves and pulling the vacuum right through, but a more convenient way is to blank your main, one section at a time, and attach a small branch from the air compressor to it. Pump up about five pounds pressure, and see how long it remains. You will soon discover the leak and can remedy each section as you go along. There remains one very important feature, the thermostatic valves. There are various types of these, some being controlled by the expansion and contraction of a volatile liquid and others by the expansion and contraction of a carbon. Those operated by the liquid usually are non-adjustable, but the carbon ones are, and if not adjusted correctly will allow steam to blow right through the coil. Now the latent heat of steam is much more than the sensible heat, but if the steam is not held in the coil till condensed, the latent heat will be given out where it is not wanted, in the return pipe. Therefore, the thermostatic valve must be adjusted so that it will remain closed unless surrounded by water. The best way to ensure this is to disconnect the union on the return side of the valve and then put steam in the coil. If steam blows through screw the carbon body down a little by the screw provided in the top, until the steam stops. Then note if it opens to let the condensation out. It should open and shut precisely as a steam trap does.

When the system is in operation send a man around to every coil at least once a week, to see that valve spindles are tight and nothing leaking on the coil itself.

These precautions will well repay the work involved by the peace and comfort obtained. A factory uniformly warm in every department, Monday morning as well as Saturday noon, will produce more and better work than one in which these conditions are not maintained.

A NEW RUDDER

A rudder of a completely novel type, which has been used on small vessels during the war, is about to be developed commercially. It is named after its inventor, Mr. J. G. A. Kitchen of Lancaster. It enables a boat to be steered, reversed, controlled and turned by a single tiller, and with the engines running continuously in the forward direction. The rudder consists of two parts which, when closed form a cone, apex pointing aft; and, when fully open, form a sort of tunnel in the wake of the screw. Whether shut or open the rudder as a whole can be turned to port or starboard like one of the ordinary kind. When the rudder is closed the propeller stream entering the open mouth is deflected forwards by the sides of the cone, brings the vessel to rest, and then moves it astern. The partial opening of the plates allows some water to pass through, and the speed and direction of the boat can thus be controlled without slowing the engines. For ordinary steering the rudder is opened fully, and deflects the propeller stream to one side or the other. It has an extremely powerful braking effect, and is capable of arresting a vessel in its own length; while its capacity for deflecting the water driven aft by the propeller renders it very useful for manoeuvring in restricted places.

Electric Furnaces in the Iron and Steel Industry; Rodenhauser, Schoenawa and Vom Baur. John Wiley & Sons, Inc., New York.

This is the second English edition of this well-known work. In it a number of changes and additional matter have been incorporated consequent upon the rapid growth of the electric furnace industry. While a considerable number of books has been written on the subject of the electric furnace, the majority of them are of such general scope that the iron and steel industry does not receive the attention it warrants. An historical resume of the development of this branch is given and is followed by a chapter devoted to the explaining of the laws and principles of electricity which enter into electric furnace work. This chapter is somewhat elementary in its scope and has been inserted for the benefit of the general student interested in this branch of metallurgy. The effects of the electric current in the production of heat by resistance, arc or induction heating is dealt with next, together with other actions of the electric current in the furnace, such as the motor and pinch effects. Chapters IV, V and VI deal with power factor and alternating current theory in general, general conditions for the operation of electric furnaces and arc furnaces in general. The various types of arc furnace dealt with are the Stassano, now practically obsolete, the Heroult, the Girod and the Pennerfelt. Induction furnaces, now little used, are also treated of. Space is given to the electric shaft furnace for the reduction of iron ore. Part II takes up materials for furnace construction and the costs of operation, and Part III, the electro-metallurgy of iron and steel. These latter two parts of this book are of value from the economic standpoint, as an exhaustive treatment is given of everything affecting the operation and economics of the electric furnace.

Next time you "light up," think of this:

About 10,000 matches are scratched in this country every second that passes, and of these 95 per cent. are used by smokers to fire pipe, cigar, or cigarette.

The man whose head for figures turned out that information also estimates that the time lost by the smokers in lighting matches—not in smoking—is worth $513,024 each eight-hour working day.

He arrives at his estimate by figuring that it takes fifteen seconds to scratch a match and use the light, and that 213,759 men, whose time is worth thirty cents an hour, are holding matches at the same time, thus losing golden minutes at the rate of $1,068 a minute, or $64,128 an hour.

No one, so far as we can learn, has figured out how large a percentage of the match-scratchers throw away the matches while they are still burning, but it has been estimated that half of the fires which cost the United States $250,000,000 a year are caused by carelessness.

Wood, phosphorus, chlorate of potash, rosin, whiting, and powdered flint are the makings of this little device.

In some anti-aircraft shells use is made of the bow wave of compressed air which is present on projectiles travelling at a sufficient velocity. In flight the striker of the fuse rides or floats on this bow wave and absolutely nothing else keeps it off the primer. The instant an obstruction, no matter how light, is encountered, the wave disappears and the striker jambs back on the primer, exploding the shell. These fuses will explode on your silk handkerchief not to mention airplane and balloon fabrics.

The discovery of helium in natural gas, both in Canada and the United States, has brought the price of this element down from over $1,000 a cubic foot to a merely nominal figure and has rendered it possible to use it for the inflation of balloons.

Accidents in the iron and steel industry have decreased by more than two-thirds during the past ten years as a result of the movement to enforce safety regulations.

The motor cycle has found use in a Hawaiian sugar factory as a heavy hauling unit or baby tractor. Four and a half tons can be hauled distributed over four cars.

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS PERSONAL AND TRADE NOTES

TRADE GOSSIP

Building Foundry. — Burnett and Crampton, Rigaud, Que., are planning a new foundry capable of turning out 250 tons of castings a month. They will install molding machines and equipment of the most modern type for producing machinery castings, mill and mining equipment and general castings.

Sault Ste. Marie.—Freight through the Soo canals shows a decrease from that in July, 1918, of 1,446,192 tons. The amount carried this July was 11,916,152. Two-thirds of this tonnage was going eastward. Of the total tonnage only 533,377 was carried through the Canadian canals.

Lachine Canal Reports.—The gross tonnage passing through the canal for July and for the season to the end of July is less than for the corresponding period of last year. A larger tonnage of grain has been moved, but the coal shipment has decreased. For the three months ending July 31 the grain carried was 10,414,989 bushels, and for the month of July 2,017,134 bushels. The coal tonnage was 36,313 tons less this July than last.

Privy Council Lowers Award.—The case between the Seattle Construction & Dry Dock Co., and the firm of Grant, Smith & Co., arising out of the loss of a drydock has been settled finally by the Privy Council. The Drydock Co. had been previously awarded $85,000 by Justice Clement and the board of assessors in the Vancouver Court. The Privy Council reduced the award to $44,500. The claim was for $150,000. The dock was wrecked when the contractors, Grant, Smith & Co., attempted to utilize it in the placing of large concrete caissons in Victoria Harbor.

Squaring Up With the U.S.—Great Britain has liquefied her munition debt to the U. S. by a payment of $35,176,123. Of this sum $13,600,000 was for Liberty motors, $13,274,000 for airplane spruce, $2,887,000 for wood distillates, $4,690,000 for powder, and $651,000 for cotton lineters.

Do Not Favor Kitsilano. — Public opinion in Vancouver is against the use of Kitsilano as a site for the terminals of the Canadian National Railways. Burrard Inlet is regarded as being eminently more suitable, and it is believed that the Government also takes this view as they are building the approaches to Burrard Inlet. A site at Kitsilano would involve the city in a large outlay for new bridges, besides spoiling this district as a pleasure resort, which is now its most valuable feature.

Going After Trade.—The B. C. and Overseas Trading Company, which was formed recently with "Expand B. C. Industries" as a slogan, is going after trade in the Orient. Mr. J. Fred Sanders, the president, has gone to China to study the needs of the market there and will send back instructions to the firm concerning the goods required, methods of packing, weights, measurement and style to conform with the customer's wishes.

To Get Canadian Goods.—Mr. Marcus Reich, of Prague, who represents the Importers' Association of Czecho Slovakia, is in Toronto to confer with the Trades Commissioner and the Canadian Manufacturers' Association. He desires to establish banking facilities and promises the establishment of a Canadian Chamber of Commerce in Prague. His country manufactures cotton goods and porcelain extensively, but require raw material and other manufactured goods.

Lumbermen Criticized.—Sir Douglas Colin Cameron, Lieut.-Col. and Lieut. Governor of Manitoba, who is also president of the Rat Portage Lumber Co., as well as being connected with other large interests through Canada, had some words of criticism for the lumbermen of B.C., on the occasion of a visit to Vancouver recently. "There are great markets for B. C. lumber," he said, "but the lumbermen have not availed themselves of their opportunities. It creates an unfavorable impression to find that the 70,000,000 feet order of lumber placed here has not yet been moved.

Valuing Fraser River Yard.—An arbitration board has been sitting in the Vancouver Court House to determine the value of the plant of the Imperial Munitions Board in the Poplar Island yard of the New Westminster Shipbuilding Co. The public sittings have been concluded but the award has not yet been given out. During the proceedings the contract between the Imperial Munitions Board and the New Westminster Co. was produced. The agreement was that the company should be reimbursed for the actual cost of building each hull, and receive a sum of $16,000 profit on each. The board consists of Mr. Justice Morrison, Mayor Gray of New Westminster, and Arthur H. Edwards.

Victoria Yards Please New York.—The success of the Foundation Company's yards at Victoria, has attracted favorable notice at the head office of the organization in New York, according to Frank Quilter, secretary-treasurer of the company. The good performances of the Victoria built ships on their trial trips has been the subject of much favorable comment. The Foundation Company are now at the height of their activity in Victoria, and the payroll amounts to over $500,000 per month.

One Engine Per Day.—The works of the Kerr & Goodwin Machine Company at Brantford, are now turning out one of the new Hoag oil engines manufactured by this company every day. There is good prospect of these engines being made on a large scale very shortly.

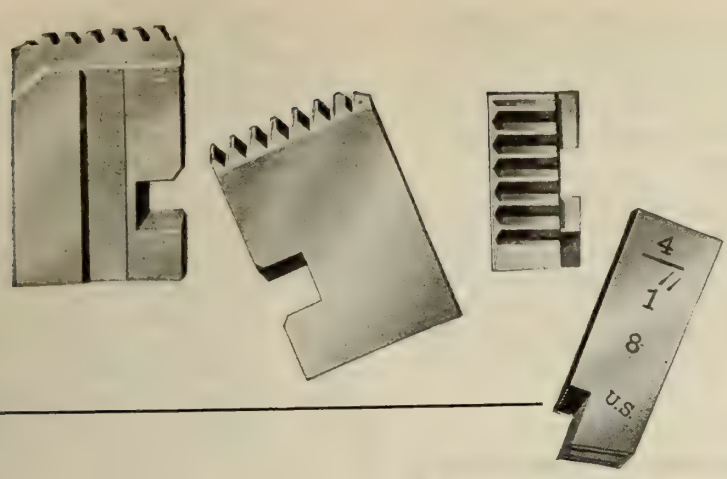
New Steel Mill.—A proposition to build a large steel plant in Belleville is now under consideration by the Tivani Steel Co., Ltd. The plant would consist of electric furnaces, rolling mills, merchant bar mills and open-hearth furnaces. A similar plant is being considered for Vancouver.

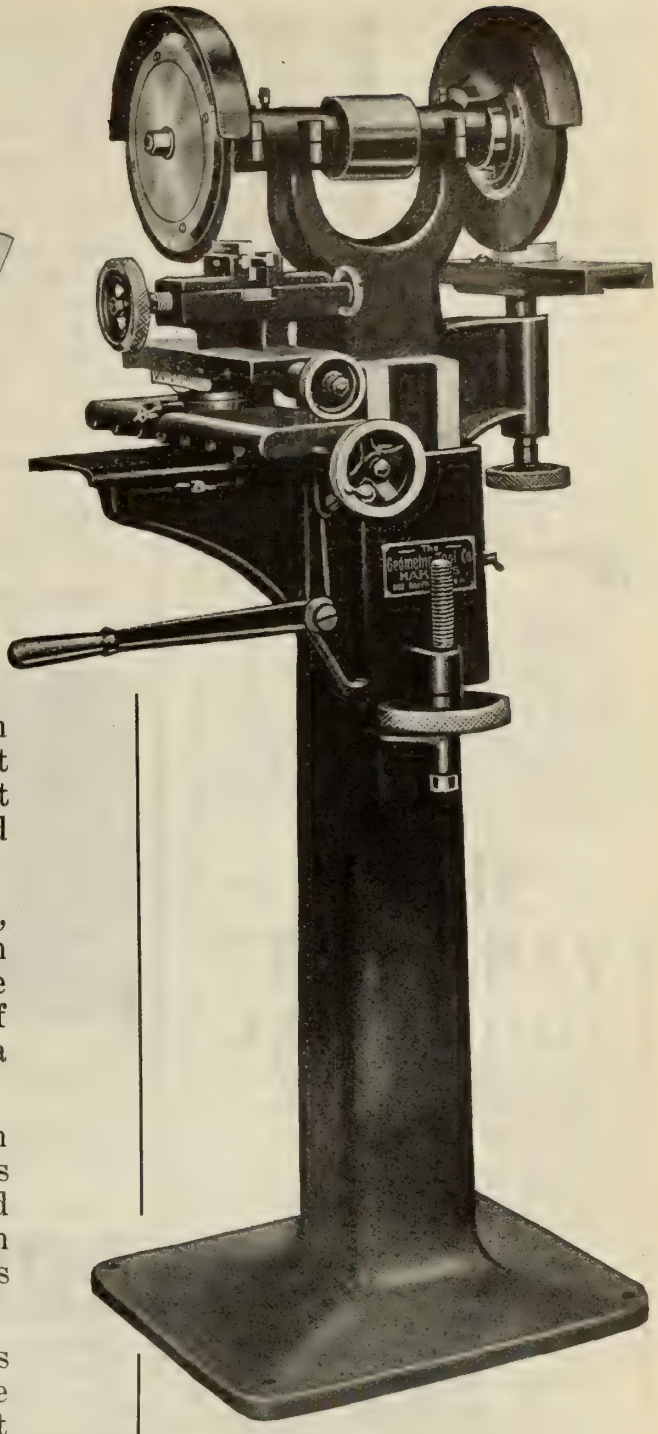
Tin Plant.—Galt is to be the site of a tin smelting plant, for which we understand a contract has been let. The idea is to build one smelter to begin with to be followed by others as the need arises.

MARINE

Halifax.—The steamer "Troja," which was recently salvaged at the entrance of the Bay of Fundy by the Maritime Wrecking Company of Halifax, has been brought to Halifax in a pretty bad condition. The repairs will be given to the firm making the most successful tender, and it is thought here that the job will go to the Halifax Shipyards Ltd., who are operating the dry dock.

Montreal.—The monthly service to be provided between Montreal and Havre, France, by the Cie Canadienne-Francaise Transatlantique was inaugurated by the arrival of the steamer "Californie" in Montreal. She brought over 280 passengers, of whom 265 landed at Quebec. The vessel left again for Havre on the 7th inst. with freight and passengers.





Sharp Chasers Cut Clean Threads

Accurate, uniform threads result only from dies which are maintained in the highest state of cutting efficiency. This means that chasers must be kept sharp, and ground uniformly.

Even if just touched up from time to time, the chasers respond splendidly, with clean threads. And with this machine — the Geometric Chaser Grinder—the matter of keeping threading tools up to scratch is a comparatively simple matter.

Various makes of chasers can be ground on this adaptable machine. The two wheels permit the easy grinding of both milled and tapped chasers. In addition, the plain wheel lends itself readily to various kinds of tool grinding.

Uniform grinding of a set of chasers is purely a mechanical matter through the use of adjustments which can be accurately set to govern the grinding of an entire set of chasers.

The Catalog describing this machine is a mine of information on chaser grinding. Write for it.

THE GEOMETRIC TOOL COMPANY

NEW HAVEN CONNECTICUT

Canadian Agents:

Williams & Wilson, Ltd., Montreal. The A. R. Williams Machinery Co., Toronto, Winnipeg, St. John, N. B.

The second steamer, the "Hudson," is expected shortly.

Victoria.—The Canadian Pacific Railway Co. are building two new steamers for the Pacific service of 20,000 tons each. One has already been launched in England and will be called the "Empress of Canada," while the second one, which has just been laid down, will be named the "Empress of Australia."

North Vancouver.—After the launching of the C-39, the last of the eight ships built for the French Government from the Lyall yards, a number of the men were laid off. There are now only about 300 men employed in fitting out the vessels already launched. The yards at one time employed 1,200 men.

Cleveland.—A large number of freighters are being held idle owing to the strike of ore dock workers at Superior. A number of vessels have loaded coal and are holding it until owners are sure that there will be no delays in unloading at Lake Erie ports.

Buffalo.—There are six freighters on the way to Buffalo with approximately 1,500,000 bushels of grain aboard them. By the first week in September the full movement of grain will be under way. Shipments of ore are increasing and hopes are entertained of a good season despite the slow start.

PERSONALS

Sergeant Paul Mitchell, of the Provisional Supply Depot, American Expeditionary Forces, France, has just returned to Chicago and has resumed his duties as travelling representative for the Independent Pneumatic Tool Company, 600 W. Jackson Blvd., manufacturers of Thor air and electric tools. Mr. Mitchell will travel out of the Chicago sales office as heretofore.

TENDERS

The Peterborough Board of Education are asking for tenders on a new school. Tenders received till September 1. Plans and specifications can be obtained at the office of the architect, W. & W. R. L. Blackwell, Room 17, Bank of Commerce Building, Peterborough.

The Toronto Board of Education are asking tenders for an addition to Keele Street School. Tenders open till August 27. Specifications and information can be obtained at the office of Messrs. Chapman & Oxley, Harbor Commission Building, Toronto.

The Norton Co. and Norton Grinding Co. have arranged to conduct their business through the Norton Co., starting July 1. A board of directors has been appointed and several other important appointments have been made in this new organization of the two companies.

The Electric Furnace Co., Alliance, Ohio, has just shipped to the Dayton Engineering Laboratories, Dayton, Ohio, an electric furnace for melting and refining aluminum in the Delco plant. This furnace has a hearth capacity of 500 pounds, and a melting rate of 200 pounds of aluminum per hour. It is equipped with a double charging door in the front and rear, and otherwise is similar to the standard Baily electric furnace of 105 k.w. electrical capacity, and 1,500 pounds hearth capacity, that is used for melting brass.

The growth of trades unionism in Canada is shown by the following table: 1911, 133,132; 1912, 160,120; 1913, 175,799; 1914, 166,163; 1915, 143,343; 1916, 160,407; 1917, 204,630; 1918, 248,887.

Heating Buildings With Electricity. There has been considerable experimenting in certain parts of the Pacific-Northwest states, where there is ample hydro electric development, with heating dwellings and office buildings with electricity, both as an adjunct to steam heat, and with electricity alone. One investigator, after considerable research, found that to compete with steam heat it would be necessary to deliver electricity to the premises to be heated at from $1.95 to $3.73 per hp.-year. With electricity at one-half cent per kw.-hr., electricity for heating is from 25 to 50 per cent. more expensive than for coal at $6.00 per ton. At one cent per kw.-hr. electricity is two and one-half to three times as costly.

ELECTRIC BRASS FURNACES DISPLACE OTHER TYPES

One Company Uses 2,500 Kw. for Melting in Three-Phase Furnaces, Another Requires 800 Kw. for One-Phase Induction Furnaces

Brass manufacturers who recently met in the convention of iron and steel electrical engineers at Pittsburgh said that they knew from experience that there are now electric brass furnaces whose metallurgical efficiency justifies their use in preference to fuel-fired furnaces. W. R. Clark, works manager of the Bridgeport (Conn.) Brass Company, spoke on the experience of his company, which has in operation a total of 800 kw. in the Ajax Metal Company's "Wyatt" single-phase, 60-cycle induction furnaces melting brass. He said that the largest furnace has a demand of 75 kw. at 75 per cent. power factor, and its pouring capacity is from 500 lb. to 600 lb. (340 kg. to 290 kg.) per hour. These furnaces have melted and poured from 6 lb. to 9 lb. (2.7 kg. to 4.1 kg.) of brass per kilowatt hour, and the linings are being used for as many as 2,000 heats each. A 75-kw. rating is not the largest for which this type of furnace can be built, but when designed for 60-cycle operation the power factor drops rapidly with increased size. The induction furnace is found to have the advantage of heating the bath from within, automatically stirs the molten metal and has very little tendency to give off spelter. However, the furnace is limited in size and has the disadvantage that it must be started with molten metal from another furnace. This latter characteristic is more of a drawback in a foundry than in a brass mill.

This Bridgeport (Conn.) Brass Company is increasing its electric melting capacity by the addition of a 1-ton (900 kg.) "Detroit" rocking type brass furnace which has opposed arcs from electrodes entering through the centre of an oscillating drum. The voltage across the arc is 65 and the maximum demand is from 250 kw. to 300 kw. per ton. This furnace is expected to melt a ton of brass with from 225 kw. hr. to 300 kw. hr. of energy. The higher consumption is for mixtures high in copper, which require a greater temperature.

It was stated in an informal discussion after the close of the meeting that whereas oil-fired furnaces are limited to a capacity of about 1,000 lb. (450 kg.) of brass each, there are now in operation "Bennett" three-phase brass furnaces with capacities up to 5 tons (4,500 kg.) of brass each. These furnaces have not yet been placed on the market, but there was said to be an installation in actual operation aggregating some 2,500 kw.

The time of flight for the shell of the long range gun which bombarded Paris was three minutes, and during the 76-miles flight the rotation of the earth added nearly half a mile to the distance. A very interesting point is that the average flight of the projectile is in a 28½-in. vacuum.

Oxy-Acetylene Welding and Cutting

Two Thousand Joints on Ten Miles of Piping made Leak-Proof at Less Cost

This illustration shows the groundwork of 2-inch ammonia pipe which forms the floor of one of the largest artificial ice rinks in the world. The size of this immense rink is 210 ft. by 90 ft. Ten miles of piping was required, and every one of the 2,000 joints was welded by the Prest-O-Lite Process at a substantial saving in cost over the old-style threaded joint. Moreover, the work was neater and smoother as well as stronger, because the welded joint is as strong as the pipe itself.

Prest-O-Lite PROCESS

has become standard practice on steel pipe lines in thousands of factories and plants. It is widely used in the construction of piping systems for steam, gas or air—in office buildings, hotels, factories, power plants, mines, machine shops and refrigerating installations.

The Prest-O-Lite Process employs both gases (acetylene and oxygen) in portable cylinders. Prest-O-Lite Dissolved Acetylene (ready to use) is backed by Prest-O-Lite Service, which insures prompt exchange of full cylinders for empty ones. Provides dry, purified gas, insuring better welds, quicker work and lower operating cost. Adaptable for oxy-acetylene cutting by the addition of a special cutting blow-pipe.

Full instructions are furnished free to every user of Prest-O-Lite Dissolved Acetylene. Any average workman who understands metal can learn the process quickly and easily. Write for valuable illustrated literature and data on work others are doing by this process, in construction, manufacturing, and repairing. It may prove to be the solution of your problems.

The Wonders of Set Number FOUR

There seems to be renewed interest in Set Number Four Johansson Gage Blocks—doubtless due to the increased interest being shown in gages generally. Johansson Set Number Four has never stopped being the wonder of mechanics wherever shown.

A number of the best toolshops now have these twenty-eight thin gages, and the opinion is that they would scarcely know how to get on without them.

Set Number Four does permit a shop to enjoy the full advantage of the Johansson System. To a user of our Set Number One, these "feeler" gages practically double the number of combinations possible. And not only this, but they permit a range of small sizes that no other set of gages in existence can give. The mechanic's particular attention is called to the gage in this set marked .010″ (one hundredth of an inch) in thickness, with two parallel surfaces and of a quality steel that will hold its size and shape.

When a mechanic gets a Set Number Four in his hands for examination, his thought is "How does Johansson produce such gages commercially?"

The sale of Set Number Four is confined to users of Johansson Set Number One as these thin gages are intended only as an addition to the big set.

Let one of our men call and show you where you can use a set of these gages. We can make immediate delivery.

FOREIGN MANUFACTURERS SEE THE IMPORTANCE OF USING

NATCO

Multi-Drillers

Increased production and economy go hand in hand wherever NATCO Multi-Drillers are given a place in the shop.

NATCO Multi-Drillers greatly increase the speed in production because they are equipped with the NATCO patented feature, namely, Independent Change of Speed for each spindle permitting tools of various sizes to operate at their correct cutting speeds.

As a result large and small holes are drilled, reamed, tapped, counterboard or spotfaced in one operation. Furthermore, idle spindles are in neutral, saving wear and power.

We also design and build jigs and fixtures for use in connection with NATCO Multi-Drillers.

NATCOS are built in 11 sizes, ranging from 2 to 72 spindles.

Let us make you production estimates.

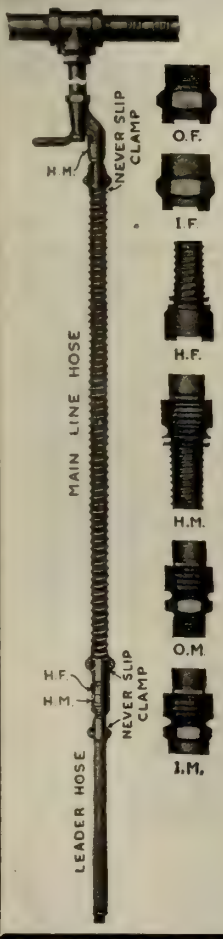
"MORSE"

WE STAND BACK OF EVERY "MORSE" TOOL LEAVING THE FACTORY. ALL TOOLS ARE SUBJECTED TO A RIGID INSPECTION BEFORE LEAVING OUR HANDS. "MORSE" TOOLS ALWAYS HAVE BEEN CHARACTERIZED BY THEIR UNIFORM QUALITY, ACCURACY AND ABSOLUTE DEPENDABILITY

MORSE TWIST DRILL & MACHINE CO.

NEW BEDFORD, MASS., U.S.A.



CLEVELAND HOSE SPECIALTIES

Bowes Automatic Air Hose Couplings

Standard Equipment Everywhere

STYLE O.F. is an Outside Thread Female Pipe End. Made in sizes ⅜-inch to 1½-inch.
STYLE I.F. is an inside Thread Female Pipe End. Made in sizes ¼-inch to 1½-inch.
STYLE H.F. is a Female Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼-in. to 1½-in.
STYLE H.M. is a Male Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼-in. to 1½-in.
STYLE O.M. is an Inside Thread Male Pipe End. Made in sizes ⅜-in. to 1½-in.
STYLE I.M. is an Inside Thread Male Pipe End. Made in sizes ¼-in. to 1½-in.
The Male and Female Ends of Bowes Couplings interchange in sizes ¼-in. to ¾-in. Sizes 1-in. and 1¼-in. interchange. The 1½-in. ends interchange only with themselves.

BOWES COUPLINGS

Are instantly connected or disconnected.
They are absolutely air-tight under all pressures.
They quickly pay for themselves by stopping costly leaks.
They interchange in sizes most commonly used.
They have no loose parts to be mislaid or lost.
They are made of brass and will not rust.
The U-shaped Gasket interchanges in couplings ¼-inch to ¾-in.

The Cleco Never Slip Hose Clamp

Made in same sizes as Bowes Couplings

The adjoining cut of Cleco Never Slip Hose Clamp shows the "Flanges" which engage the groove provided in all hose ends of Bowes Couplings. The "Model Hose Line" illustrated shows correct styles of couplings and valve to use and proper way to attach the clamps.

CLECO GROOVED HOSE NIPPLE

Grooved Nipples when attached to hose with the wire clamp cannot "blow-out," as one-half of the Wire Clamp lies in Nipple Groove, and the other half on the hose, uniting nipple and hose permanently.

WIRE CLAMP TOOL

To apply Wire Clamps to Grooved Hose Nipples you need the Wire Clamp Tool illustrated, a small hand-operated tool at moderate cost which we carry in stock for immediate delivery. In Stock: Riveting and Chipping Hammers, Four-piston Air Drills, Corner Drills, Emery Grinders, Sand Rammers, Holder Ons, etc.

Use Annealed Wire No. 14

Write for Bulletin 38 illustrating Cleco Hose Fittings, Couplings, Valves, etc.

IMPORTANT:—The Small Leaks in your "AIR LINE" mean serious loss in DOLLARS. Have you any idea of the amount of "Air" wasted in small leaks at your connections? Air Leakage through 1-16 in. opening equals 5.32 cu. ft. per minute at 80 lbs. It will pay you to install Bowes Couplings and stop costly leaks.

Write for Bulletin 34A, 41 and 43.

"Williams' "Vulcan"
Drop-Forged Safety Lathe Dogs

WHEREVER Lathes are used it is conceded that, no matter how good the machine tool may be, poor equipment makes its satisfactory operation difficult, if not impossible.

Why employ inferior equipment?—the best tools are always the cheapest in the end.

Williams' "Vulcan" Drop-Forged Lathe Dogs are absolutely safe and dependable. Their design, material and workmanship are the result of nearly half a century of constant effort to produce the best and only the best. Bent and Straight Tail—one or two screws, 16 sizes, 3/8 to 6 inches maximum capacities.

May we send you a copy of our Machinists' Tools Booklet ?

J. H. WILLIAMS & CO.

"The Drop-Forging People"

Western Office and Warehouse:
45 So. Clinton St., Chicago, Ill.

Rockford Horizontal Boring Machine

For Automobile Manufacture

This tool is unusually rapid and accurate in the boring of crank cases, transmission cases and rear axles. Has two heads at right angles to each other. Spindles bore longitudinal and cross holes in work simultaneously.

Send us blue prints of your boring work and we will give you figures on the "Rockford's" ability on it.

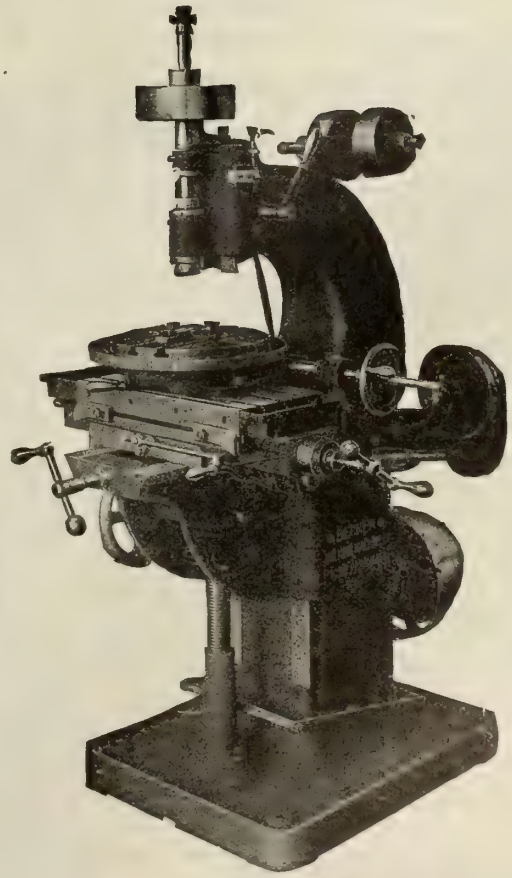
You Need a Miller At Once?

Then you're lucky, for you can choose from a wide range of smaller type

BECKER MILLERS



all well adapted to milling rapidly small and medium parts.

Stock for quick shipment includes Nos. 1, 2, 2H, 3 and our No. 25 Plain Horizontal Miller, also the machine illustrated, which is a No. 2A vertical.

You'll notice we've taken it for granted that you know the enviable reputation of Becker Milling Machines. But if you don't, let us send you catalogue and some plain facts about quantity production to expect.

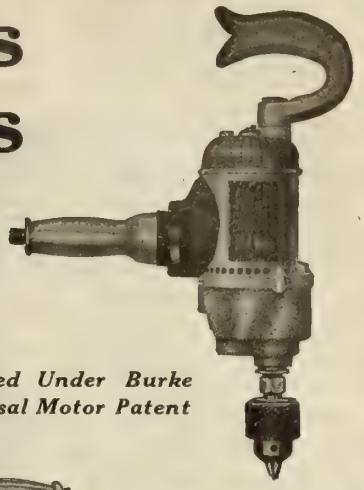
Thor

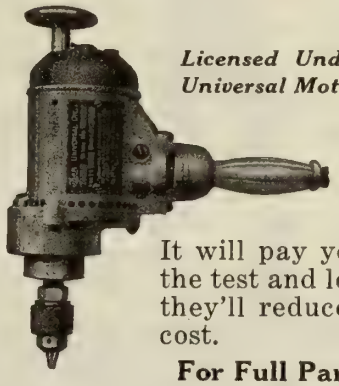
Electric Drills and Grinders



The only Electric Tools equipped throughout with ball and roller bearings.

Light, Powerful and Durable.

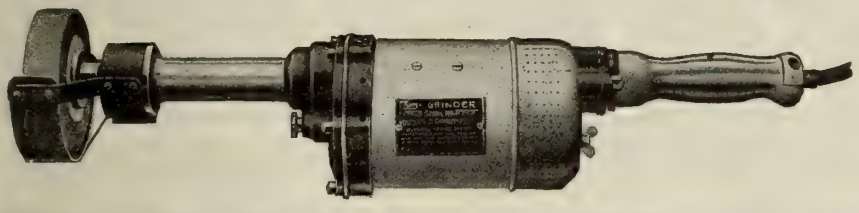
Thor Electric Tools have off-set spindles —which permit operating in close quarters—a variety of speeds, S K F Ball Bearings, four contact switches, D.C. or Universal Motors and several other features that make them the super-tools of the day. Jacobs Chucks used as Regular Equipment.



Licensed Under Burke Universal Motor Patent

PORTABLE ELECTRIC GRINDER

Equipped with Universal Motor for Operating on Direct or Alternating Current 110 TO 250 VOLTS



It will pay you to put them to the test and let them prove that they'll reduce your production cost.

DUNBAR SPRINGS

ACCURACY ASSURED

You can always depend upon Dunbar Springs being **accurate.** Before proceeding with any order the first few springs are carefully tested and checked up for this very purpose.

Seventy-two years' experience making flat and spiral springs of every description enables us to furnish you with springs of the highest quality, that can be depended upon under all conditions.

Send blue prints for estimates.

STAR TRADE MARK REGISTERED

You use big lathes for big work. Isn't it just as logical to use a small lathe on small work which requires accuracy.

It is true that small work can be done on many big lathes, but think of the immense overhead expense for a small job and the big floor space and extra power a big lathe requires.

Conserve Your Power and Space

PUT YOUR SMALL WORK UP TO A SMALL MACHINE

STAR TRADE MARK REGISTERED

Base your figures in "tar" Lathe accuracy and you will realize that there is much work that can be handled far more cheaply than is now thought possible.

Sizes, 9", 11", 12', 13" swing.

May we send our Catalogue?

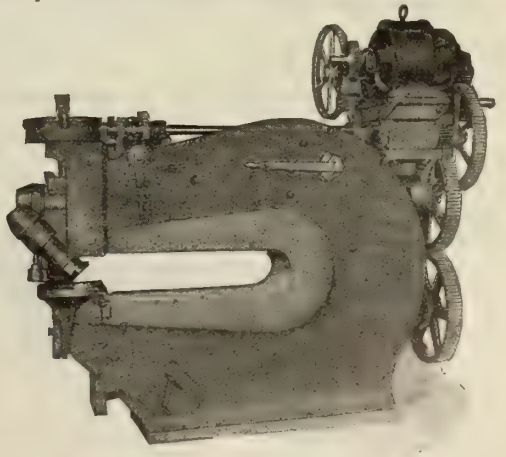
"QUICKWORK"
Registered U.S. Patent Office

ROTARY SHEARS

Made in 6 Sizes

Cut all gauges of sheet and plate metal up to 1 inch thick in straight or irregular shapes and openings without cutting in from side of sheet. Leaves square, true edge that requires no finishing. Used in building ships, boilers, tanks, cars and general plate and sheet metal work.



Patented June 3rd, 1913

SAVES 50% TO 90%

Eliminates Oxyacetylene Cutting and Plate Planing

WRIGHT HOIST

There IS a Difference in Hoists

BECAUSE their cost is small as compared with any other important piece of machinery, chain hoists are too often bought indiscriminately, as you buy rope. There is a difference in hoists, however, and a difference which becomes very important when you stop to consider them from the standpoint of speed, efficiency and safety. This is the test of any hoist.

Wright hoists have been standing these tests for as long as fifteen years under actual service conditions. They are better than ever today, with fifteen years of exclusive hoist manufacturing experience embodied in them.

If you will buy your next hoist with the same care as you would buy any other important piece of equipment, after the same thorough investigation your choice will be the Wright.

Write for our latest catalog of Wright Hoists, Trolleys and other lifting equipment.

Whitcomb-Blaisdell Planers

WHITCOMB-BLAISDELL LATHES AND PLANERS PLAY SOME PART IN THE MOST OF THE HIGH-GRADE MACHINE TOOLS MADE ON THE CONTINENT.

ALL-ROUND machines for high grade work, they are equipped with special labor-saving attachments that add to their convenience and enable the operator to "speed up" without endangering accuracy.

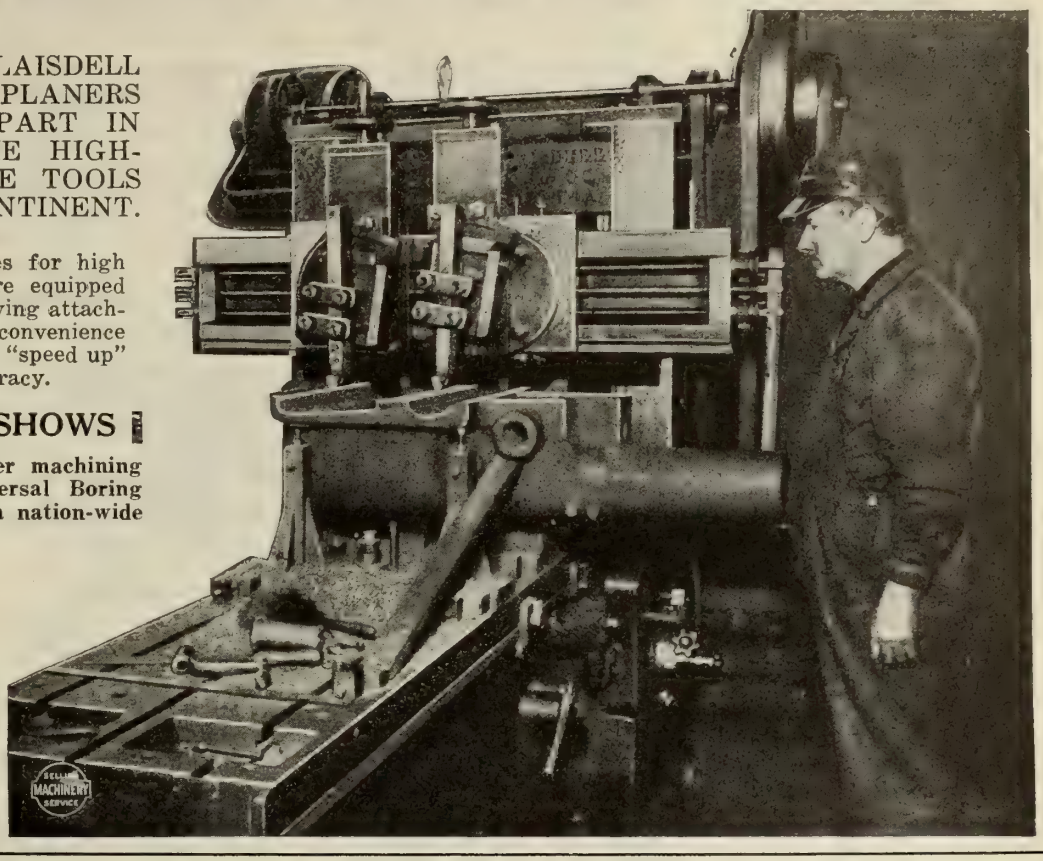
ILLUSTRATION SHOWS

a Whitcomb-Blaisdell Planer machining the head post of a Universal Boring Machine—a machine with a nation-wide reputation for accuracy.

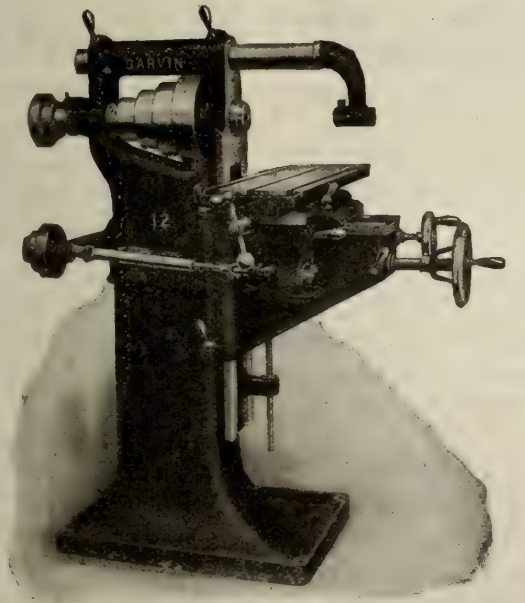
May we send you our catalogue giving full particulars?

Whitcomb-Blaisdell Machine Tool Co.

WORCESTER, MASS. U.S.A.



GARVIN



No. 12 Plain Milling Machine-Use Code Abrade

NO. 12 PLAIN MILLING MACHINE

FOR ALL LIGHT MANUFACTURING

This machine is built especially strong and substantial for a tool of its capacity, and has many valuable features worthy of special mention. The slide is fitted with a quick pitch screw, giving one inch per turn. This combines the rigidity of a rack feed with the steadiness of the screw feed. The table has an oil pan all around it, with finished edges—automatic feed, trip and reverse—adjustable nut on the feed screw to take wear—the Feed Screw is hardened.

Adjustments .....18 x 6 x 15 in.

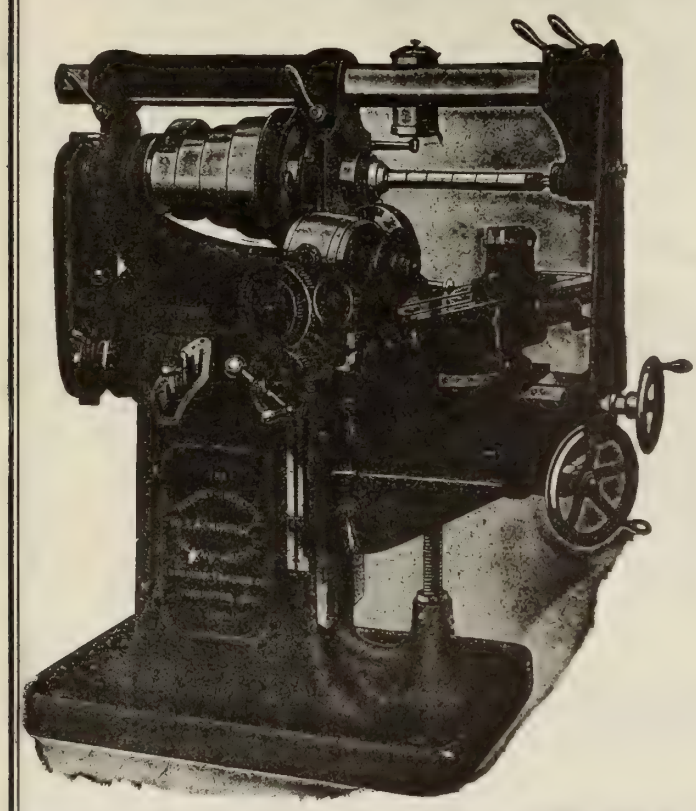
Anybody Can Operate This Miller



and Turn Out a Pile of Work so Simple to Operate is the

"HENDEY"

Skilled mechanics are scarce these days—but anyone can run a machine of its simplicity and turn out work accurately and fast without trouble.

All Feeds positive driven through gearings giving 18 changes.

This is the universal type—designed to handle all milling operations performed on machines of this character, either with regular equipment or by aid of attachments, which can be supplied for increasing efficiency and scope of machine.

Gray Planers

Gray Planers are built by a firm that makes nothing but planers. They are given the entire time and attention of a large organization—and their performance shows it.

The parts are so proportioned and the metal so distributed that the planer is quick acting and simple in operation, and yet sufficiently stiff, strong and powerful to perform a great portion of the work for which larger, heavier and more clumsy planers are ordinarily used.

Superior Grinding Wheels

Fast and Cool Cutting, Durable and Uniform. Vitrified Silica or Semi-Vitrified and Elastic Process.

"FOSS" Service gives special attention to using the right wheel in the right place. We have a large stock of shapes and qualities on hand for prompt shipment.

Wallace Bench Planer

The Wallace Bench Planer designed especially for small work. It is the quick action machine you need to turn out that bulk of your planing, surfacing, beveling, jointing and fitting efficiently — economically.

It is portable—works right on the bench—handy at the elbow of your men.

It "Speeds up" production and cuts cost.

Link Up with Foss Service and Quality

It will result in a very satisfactory connection

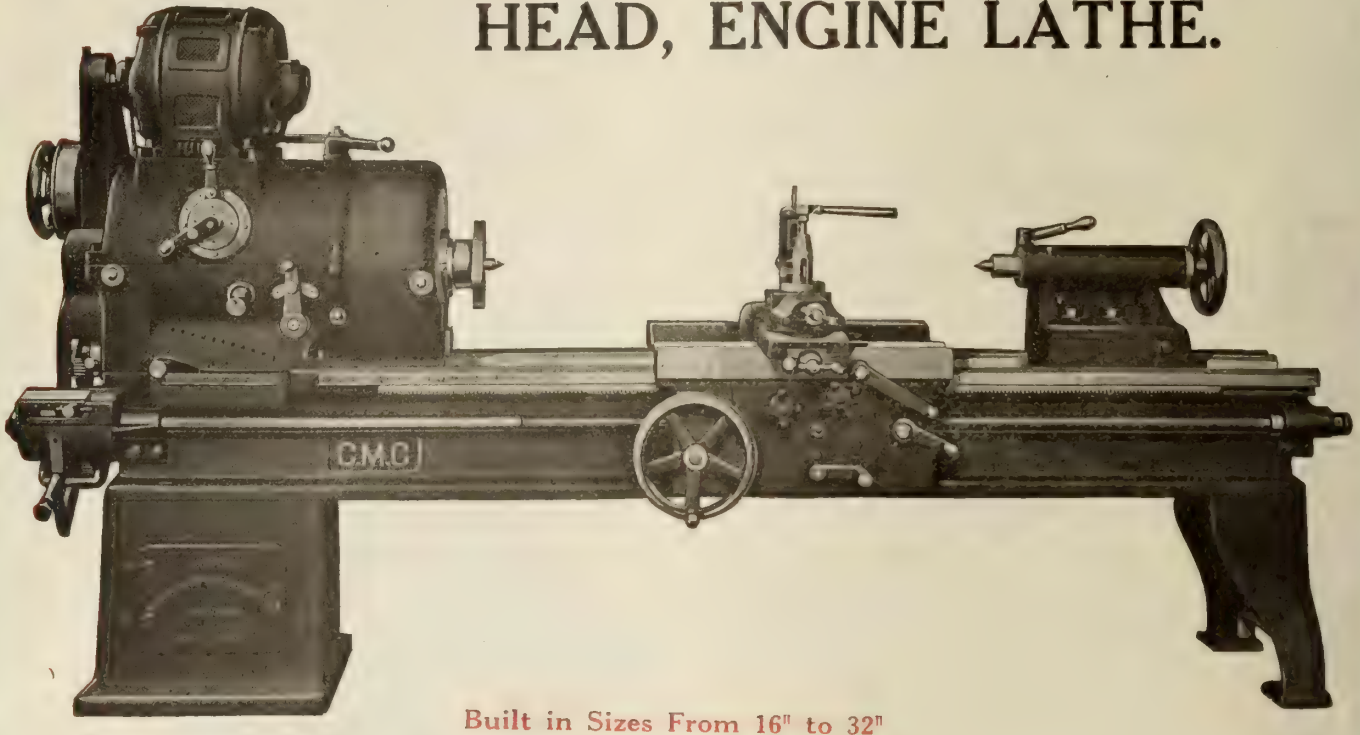
ADVANTAGES OF THE C.M.C. MOTOR DRIVEN ALL GEARED HEAD, ENGINE LATHE.



Built in Sizes From 16" to 32"

This Lathe has many advantages over the belt driven machines and other all geared lathes.

You place the machine, attach the wires and commence operation. You may place it where and how you like, regardless of shafting alignment or position—where it is most convenient or least in the way of other equipment as your fancy suits.

You may operate it at will—when all other machines are still for that matter. It is the thing for over-time rush jobs or repairs.

There are no belts to catch clothing or fingers.

Headstock—Eighteen speeds are obtained with only thirteen gears, giving a maximum number of speeds with a minimum number of parts, as many eight and twelve speed heads have as many or more gears than this design.

(Photograph by courtesy of our customer)

Blanking, cupping and stamping electric light wiring device parts in the Arrow Electric Company's plant at Hartford, Connecticut. Steel, brass, copper and pressed paper stock, 1/64 to 3/32 thick is used. The company began to install "Bliss" Presses about 10 years ago. It required a high rate of production on a variety of small parts. It now has in operation over one hundred "Bliss" Machines and is getting the production it wants.

Purchase the Products of Canadian Mills

TO uphold the Glory we have jointly earned—to honor our noble dead—to comfort the wounded, and extend to the men returned the hand of prosperous welcome, we must cast aside all forebodings and face the future with unbounded courage and confidence and, without a shadow of doubt, declare to the World that this Nation, which was so quickly and successfully transformed to a War basis, can be depended upon to revert to Peace conditions with equal success. The buyer and seller must recognize their duty to the Nation and co-operate fully to the end that all products that can be produced in Canada by Canadian workmen shall not be purchased elsewhere.

OUR Duty is plain; Canada with Canadian labor and capital can produce, manufacture and distribute products sufficient to keep the wheels of industry turning to the limit. The song of Prosperity and Happiness should ring out all over the land. Let us sincerely pledge to the extent of our needs, to purchase materials produced in Canada by Canadian Workmen, and the result of our efforts will return to us the Blessings of a Prosperous and Happy Nation.

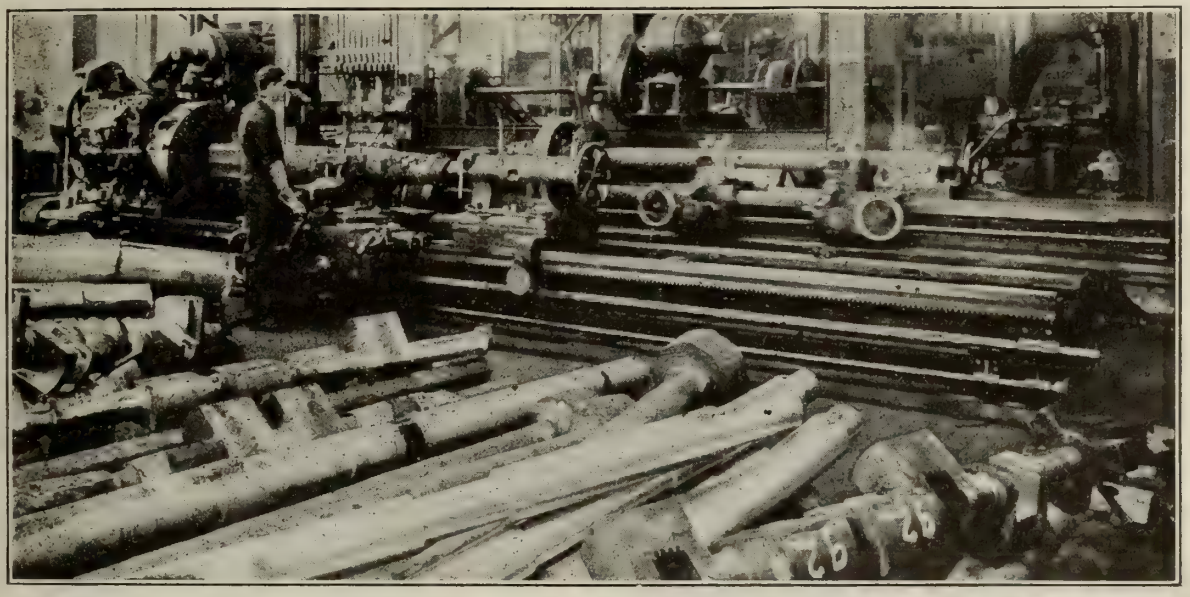
BRIDGEFORD

Heavy Duty Lathes



The above photograph shows a Bridgeford 27″ Manufacturing Lathe finish boring a cast-iron transmission housing for the new Fordson Tractor.

The diameter of housing is 19⅛″ and the limits of accuracy are .002″.

Maximum production is a requirement in the Ford plant and that is why a Bridgeford was selected to do the work. The Bridgeford turns out 80 pieces per day of 8 hours, which is excellent production.

There's a Bridgeford for every heavy duty lathe requirement. Bridgefords are in operation in all parts of the world on all kinds of duty. The line includes Heavy Geared Head Engine Lathes from 24″ to 72″ swing, Cone Driven Engine Lathes, Axle and Journal Truing Lathes and Manufacturing Lathes of 27″ and 30″ Swing.

Send for interesting data on Bridgeford Lathes.
We are in a position to make prompt deliveries.

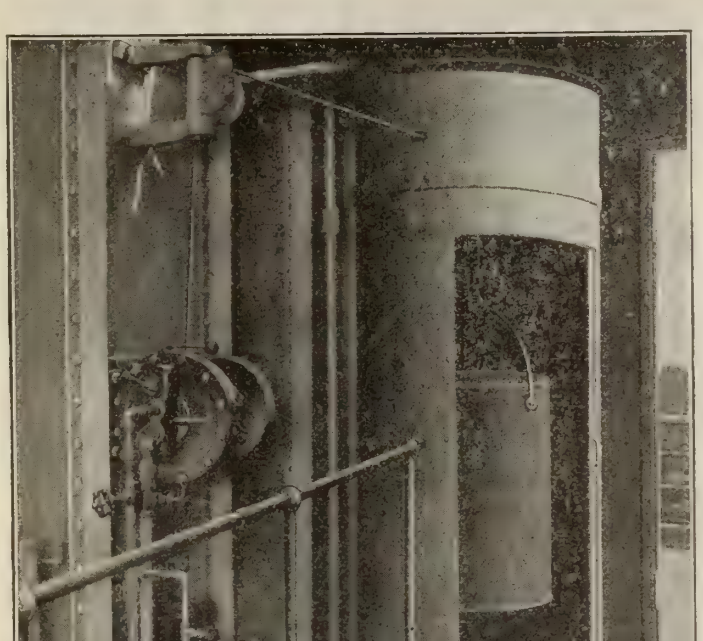
BRIDGEFORD

The "Little Tugger" Hoist on Shipboard



As an ash hoist the "Little Tugger" saves a great deal of hard work. It is extremely simple, remarkably compact, and has no projecting parts whatever. The "Little Tugger" is powerful, speedy and has a strong band brake, giving complete control.

Bulletin 4333, and "Billyisms" show many other uses for "Little Tugger" in the shipyard and in construction work.

Represented in Canada by Messrs Norton Callard & Company MONTREAL Que.

Illustration shows a Wilt Twist Drill in active service at the new shops of the Canadian National Railway, Leaside, Ontario.

Wilt Quality improves production and cuts drilling costs to a minimum.

This is no theory, no untested statement, but an established fact backed by many of the largest manufacturers throughout Canada. For steady, reliable output of work that is satisfactory from the standpoint both of quantity and quality there is no better choice than WILT products.

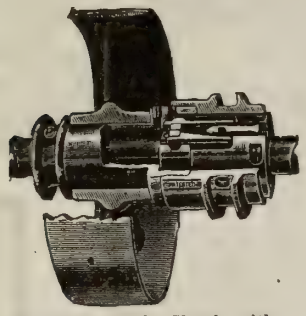
Manufacturers of a paramount line of Twist Drills, Reamers and Milling Cutters

THE JOHNSON FRICTION CLUTCH



Standard Single Clutch with Pulley Mounted on Hub —Clutch Engaged.

MANUFACTURERS who are particular about keeping an established reputation equip all their machines with Johnson clutches. They recognize that superiority must be consistent in order to count. And Johnson clutches assure them of uniformly good service wherever they are installed.

Other clutches might work well in some cases —but Johnson clutches are *sure* for all purposes. We study each application on its own conditions, and build a clutch that is just right for the job.

When you are tired of experimenting, let us have a chance.

Starrett

Hack Saws

Cut faster!—repeated tests have proven the soundness of the Starrett system of designing different blades for different classes of work. It's the number of strokes to the cut that determines the comparative efficiency of blades—the number of cuts to the hour. And it is the ability of the Starrett blade not to only complete the cut with the minimum number of strokes, but to deliver a greater number of cuts during the life of the saw, that has made its reputation.

To get the most out of a box of Starrett blades, use the Starrett Hack Saw Chart 3, sent free upon request.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25%; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood pattern-makers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us.

Scene in the Haley Mill Showing Goodyear Extra Power Belting in Use.

Another Convert

HALEY & SON,
Lumber Merchants

Gentlemen:—

We want to tell you about the Goodyear Extra Power Rubber Belting we bought for our new mill two years ago and what great satisfaction this Belting has given us. As you are aware, we bought this kind of belting from you for the equipment of our mill **throughout,** even to planers and matchers. We were skeptical at the time about using this belting on our matchers, especially on the side heads, as that is a very trying place for any kind of a belt. We concluded we would try your rubber belting, as we thought then as a makeshift. Now it has been something over two years since we belted up our matchers with your belting and the original belts are yet on these machines and still giving good service. We thought where this belting of yours had proved so eminently satisfactory that we should tell you just as we thought about it and you know we are giving you this testimonial of Goodyear Extra Power Rubber Belting entirely at our own initiative.

Yours truly,
HALEY & SON.

GOODYEAR
MADE IN CANADA

Almost Unbelievable Power-Saving and Economy

Time and again we have found purchasers of Goodyear Extra Power Belting openly skeptical that it would live up to our promises.

Time and again they have told us not only of lower belting costs, but also of increased and faster production, time and power saved.

To-day there is no reason for any plant to buy belting on promises.

On file in our office are letters which enable you to buy belting by proof.

Records of Goodyear Belting performance.

Records of extreme long-life, which means economy.

Records of pulley-gripping, non-slip qualities which save power.

Records of work under strenuous conditions of heat, cold, damp, acids.

Records of strength and flexibility.

Records which prove that without Goodyear Extra Power Belting enough power is wasted in Canada every year by poor belts to pay a big dividend on Industry's capital.

Some of this power is being wasted in your plant. Better belting, scientifically applied, will save you money. Without obligation to you, a belting man, trained by Goodyear, will call and make a record of your needs and experiences. Our recommendation will come from engineers who fit belts to conditions. Phone, wire or write the nearest branch.

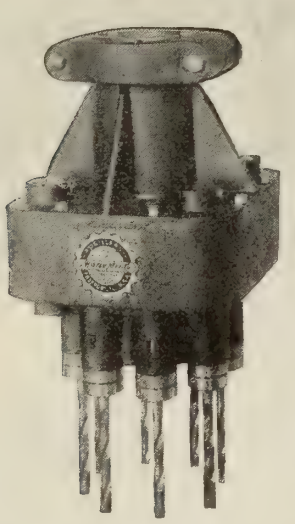
EXTRA POWER BELTING

2 Minutes or 20?



This Is The Vital Question

Do you drill ten holes in the time it takes for one? The Hoefer Auxiliary Head equips any driller so as to accomplish this big saving in time. It speeds up production in drilling tremendously. Not only do you save the drilling time, but also the time now lost in shifting the jigs and raising and lowering the spindle for the extra holes.

Hoefer Auxiliary Heads are made in any multiple, arranged in any manner, from 2 up. They are made by expert tool makers and unqualifiedly guaranteed to handle accurately the work for which they are designed.

Investigate now—every day you use a single drill where the multiple may be used you are paying for an auxiliary head through increased costs, but not securing its benefits.

Write for catalog. Send a blueprint of some of your work for estimate of time cost.

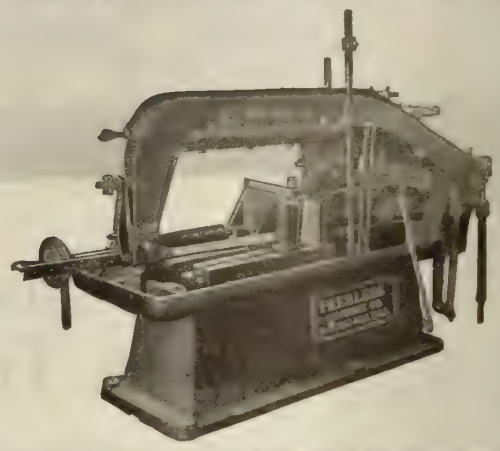
Peerless HIGH SPEED

Has Proven Its Efficiency Where Others Have Failed



DON'T turn down the "Peerless" because you have tried out other hack saws which did not answer your requirements.

Many concerns who were persuaded only with the greatest difficulty to try their first "Peerless," because they "just knew it would turn out like the others," are to-day among the largest and best-satisfied users of our High-Speed Saws.

The "Peerless" is different—and better. It does 50 to 100 per cent. more work, cuts with thinner saws and requires a minimum of attendance, saving time, labor, material, blades and floor space. What is your work? We can tell whether the "Peerless" will do it, and back our judgment with a 30-day trial. If it doesn't make good we pay freight both ways. Well?

PEERLESS MACHINE CO.

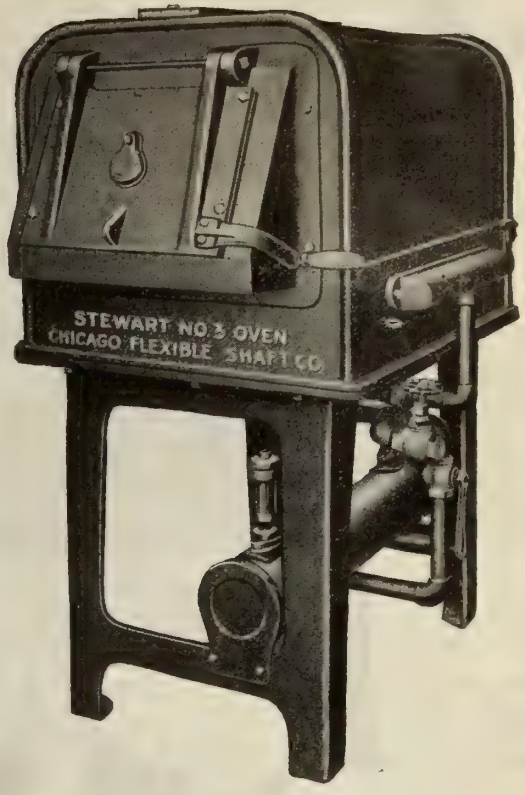
Gas Furnace Triumphs Over the Electric at Providence



Competition is keen in Providence, R.I., and therefore both the Electric Company and the Gas Company employ the best brains and selling talent on the market.

An Electric Furnace was recently installed in the Tool Room of a large manufacturing plant in that city, and it looked like a real triumph for the Electric Company, as the Gas Company, also, had been hot on the trail.

But the Gas Company wasn't discouraged.

They advised the customer to give the electric furnace the fairest kind of a trial.

They didn't knock.

But they did do a lot of figuring of costs, and the result was so convincing that the customer agreed to the installation of a Gas Furnace, on trial, and then things got exciting.

The Customer, the Gas Man and the Electric Man all three watched and checked the performances of both furnaces.

Here is what they found out:

1. The Electric Furnace was costing $20.00 per week.
2. **The Gas Furnace was costing $13.84 per week.**

The Gas Furnace has replaced the Electric in that Providence factory.

Stewart Gas Furnaces and Ovens

are doing more every day to demonstrate the superiority and the economy of Gas for Industrial uses over the use of electricity than any other one factor.

Is your Industrial Department aware of this, and if so are they using the information in your business-getting campaign this year?

There are over one hundred types of **Stewart Gas Furnaces and Ovens** being manufactured and sold to-day. Send for our illustrated catalog.

BUILT IN TWO SIZES 8" and 12".

The New Surface Grinder you have been looking for

The new HEALD No. 20 and No. 22 MACHINE is a simple, productive and accurate rotary surface grinder. That the new machines meet the first requirements can be seen from the photograph above.

In regard to production and finish, experiments have proven these new machines have no equal in the field to-day.

The WHEEL SLIDE is a massive casting having a flat and "V" way insuring continued alignment. Bearing surfaces are large and well protected. Spindle belt operates with a downward pull; an important factor in rigidity.

The chrome nickel WHEEL SPINDLE is mounted in large bearings, all adjustments of which are made at grinding wheel end through an opening in top of slide.

The MAIN DRIVE UNIT receives power from the main line by tight and loose pulleys, transmitting it directly by belt to main speed box, wheel spindle and pump.

MAIN SPEED BOX, situated on the rear of machine, furnishes power to wheel slide by a 3-step cone, and operates the chuck, which has three speeds, through a bank of gears. Wheel slide and chuck are independent of each other, permitting a large latitude in speeds and feeds.

Chuck spindle is driven by spiral gears, one of which is mounted directly on the spindle. Spindle itself is mounted in a sleeve which has vertical adjustment. Upper portion rests in a taper bearing, lower end being equipped with ball bearings—wear is automatically taken up. All control levers and adjustments are within easy reach of operator.

Complete water apparatus is furnished with each machine; built in two sizes, 8" and 12", with Heald Magnetic Chucks are regular equipment. Motor drive if desired.

LET US SEND YOU SPECIFICATION AND LITERATURE

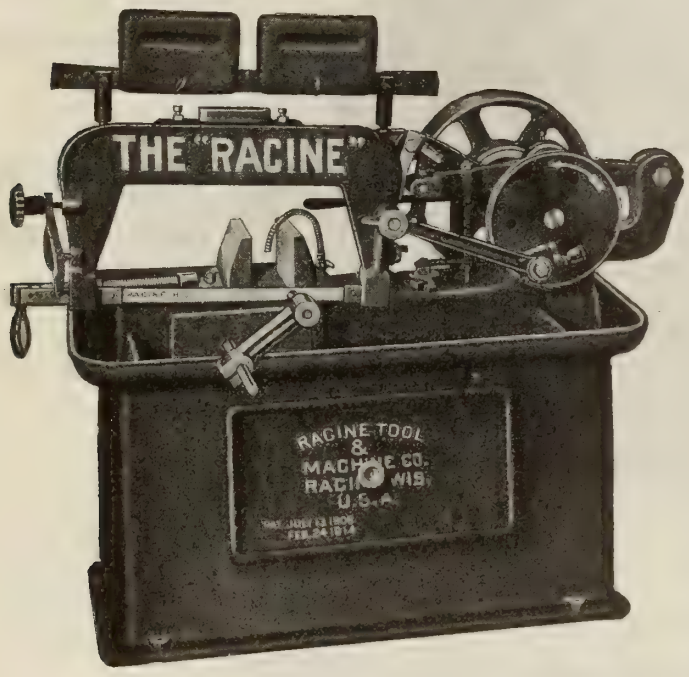
Standard the World Over

"THE RACINE"

HIGH SPEED METAL CUTTING MACHINE



Reduces Blade Expense

Aside from its ability to turn out more work than any other metal cutting machine, "THE RACINE" will save you considerable money on blades alone—enough to pay for itself in a reasonable time. The automatic lifting device is responsible for that. It automatically raises the blade on the return stroke, relieving it of all dragging or strain. This also means quicker cutting, less power used and greater production.

There are many ways "THE RACINE" will prove a big saving. Let us tell them to you.

Notes On Grinding

NORTON COMPANY WORCESTER, MASS.

No. 62A

Use Wheels of Large Diameter for Snagging Castings

SALESMAN'S COMMUNICATION

"One of our customers has raised the question of whether the diameter of a wheel will have any bearing on the cost of grinding, especially so on heavy work like steel castings. This customer in question uses 18" diameter wheels on swing frames. Kindly advise me if you have an actual data on this."

THE REPLY

We have no actual figures to show what the effect of wheel diameter is on the cost of snagging castings, but perhaps a brief general discussion is in order.

To take an extreme case, we would hardly use a 4" diameter wheel to snag castings, for the principal reason that you could not remove metal fast enough. Under usual power conditions for a 4" wheel it would slow down and stop just as soon as any considerable pressure was put upon it. Now an 18" diameter wheel, driven with proportionately larger belts and greater motor power, would have sufficient momentum to keep going, even under great pressure. There is no question that theoretically there is something to be gained from this flywheel effect which keeps the speed up and hence tends to reduce the wheel wear.

Another point is worth considering, and that is the arc of contact. The larger the diameter of the grinding wheel, the more cutting grains are at work each second, due to increased arc of contact. This makes for two things—faster cutting and less wheel wear.

Still a third factor is the greater economy in abrasive consumption that always exists when the grinding wheel is large and up to speed. Say that a steel foundryman is snagging drawbars with an 18" diameter wheel. Each drawbar ground requires an average abrasive consumption of about 2 cu. in. Now a wear of 2 cu. in. on an 18" diameter wheel represents a much less reduction in diameter than a wear of an equal amount on a 14" diameter wheel. The more a wheel reduces in diameter for each piece ground, the less its surface speed and the smaller the arc of contact. Unless the correct surface speed is maintained almost absolutely, both of the factors mentioned tend to make the grinding wheel wear out fast and hence lower its efficiency.

Now, these considerations are somewhat theoretical, but sound. They point to the use of as large a diameter grinding wheel as can be employed, taking the type of machine and the strength of the operator into consideration. We should advise the use of at least 18" diameter wheels on the swing frame grinding machines, and larger if within the limits that the machine operators can stand.

Our customers buy wheels for this purpose ranging from 16 to 24" diameter, the majority being 18" and 20" diameter.

Agricultural Machinery Manufacturers! Here's Something for You

The Norton Grinding Company can help you keep down your manufacturing costs, improve the quality and finish of many of your products, and increase the output.

One of the best known agricultural machinery manufacturers uses large numbers of bronze bushings for connecting rods in a large 75-h.p. motor built by them. This concern finishes them on a 6 x 32-in. Norton Grinding Machine. The operator removes 1-32 inch stock and is allowed a tolerance of 0.001 inch. His average output is one every minute. Our Service Department will gladly furnish you with information on plain grinding. Perhaps you have work that could be done more profitably that way. Send us your blue prints.

MATTHEWS Pittsburgh Bevel Steel Letters and Figures

Hand Made

Matthews' Letters and Figures are hand made from carefully selected tool steel. The characters are neatly formed, producing stamps that make easily read and durable marks on all classes of products. They reduce considerably the cost of high grade marking.

Try them! Mark your next order — "MATTHEWS' Letters and Figures."

Steel Lettering, Dies and Stamps

Every Emery Wheel With Its Own Dresser

Desirable, isn't it, now that cost is no objection? For with an inexpensive Desmond-Stephan Dresser for every wheel, every wheel will be touched up frequently and so kept true and equal to its original cutting efficiency.

For all ordinary shop grinding wheels specify **"Diamo-Carbo"** —the perfect diamond substitute.

For large, coarse, hard wheels ask for the **"Desmond-Huntingdon."**

Sherman Corrugated, 2 sizes
Norton Zig-Zag, 2 sizes

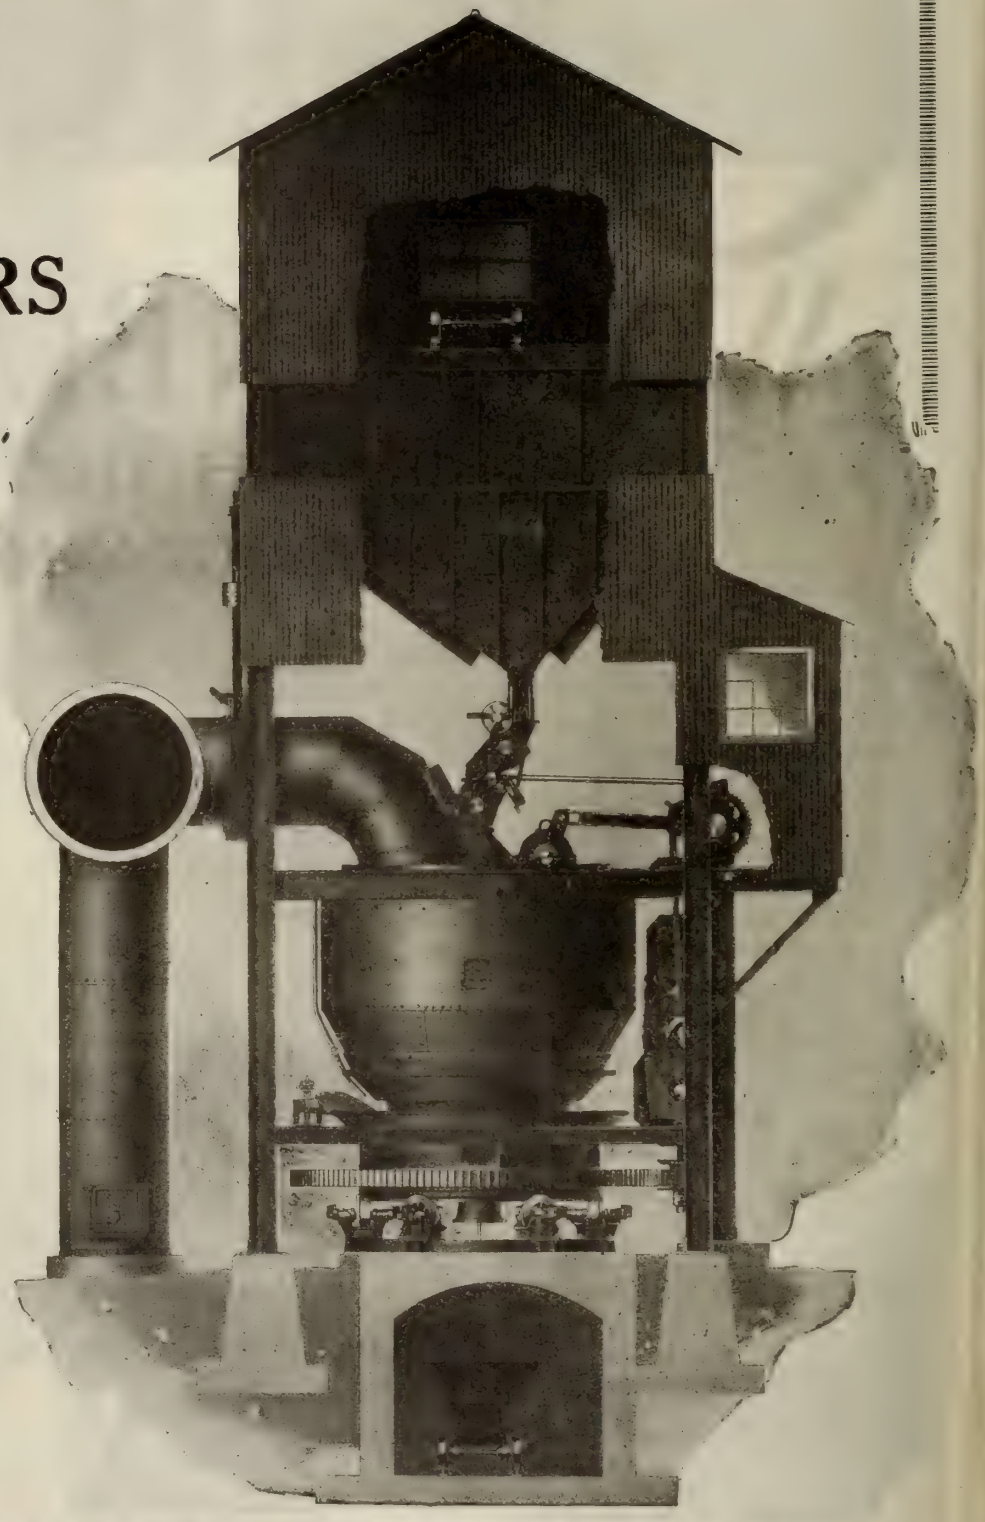
HUGHES MECHANICAL

GAS

PRODUCERS



THE Wellman - Seaver-Morgan Company is prepared to install complete producer gas plants—including building, producers, coal and ash-handling equipment, gas flues and valves, or it will supply the gas producer alone.

The W-S-M organization with many years' experience in this line have incorporated in the Hughes Gas Producers correct mechanical principles and excellent materials—resulting in a producer that assures uniformity of performance, low maintenance cost and a minimum labor charge.

A new bulletin giving a detailed description of this producer has just been issued. Shall we mail you a copy?

Reducing Press Accidents by Sane Treatment

Through the Courtesy of the National Safety Council We Are Able to Present to Our Readers Photographs of Various Safety Devices on Presses Which Have Proved Most Successful

ACCIDENT records show that more injuries occur on power presses than on any other machine, except, perhaps, the circular saw. This pamphlet will discuss especially the metal-working press, or "punch press," the use of which is so rapidly increasing; but many of the principles herein described can be applied, with a little ingenuity, to similar machines in specialty manufacturing, leather working, printing and binding, soap making, and other industries.

Causes of Accidents

In practically all press accidents, the operator's fingers are caught under the ram, at the point of operation. This is due to (1) the press repeating, (2) the operator leaving his hand between the dies as the ram descends, or (3) an unexpected stroke caused by accidental tripping.

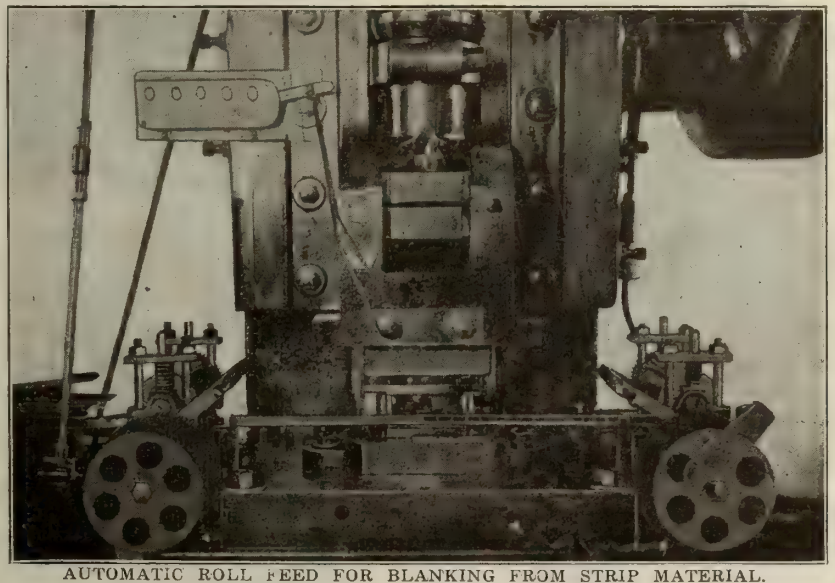
The report of the Industrial Commission of Wisconsin for the year 1917 shows that of 343 punch press accidents, 333 (or 97 per cent.) occurred at the working point, and that of 111 permanent injuries resulting from these accidents, 110, or over 99 per cent., occurred at this point.

Over 99 per cent. of the cost of these accidents, including compensation and medical attention, was chargeable to accidents occurring at the point of operation. This is convincing proof that to prevent press accidents a study of the operation of each press must be made, to eliminate, if possible, the need of the operator placing his hands between the dies; or, if this is impracticable, to install a guard which will prevent the operator's hands being caught between the dies when the ram descends.

Automatic Feed

The most effective way to remove the operating point hazard is by using an automatic feed. It is difficult to develop a satisfactory feed for some operations, but if the problem can possibly be solved, a marked increase in production (as well as safety) will result. Types of automatic feed include the following:

(a) Roll Feed. This may be used in most operations where strip metal is passed through the press for blanking. These rolls, driven by small gears, or by a belt, feed the stock through the machine, and the operator's hands need not be placed between the dies.



AUTOMATIC ROLL FEED FOR BLANKING FROM STRIP MATERIAL.

(b) Plunger Feed. The plunger pushes the work under the ram at each stroke; the operator places the work in a vertical feed chute, the plunger operating at the bottom of the chute.

(c) Chute Feed. The press is inclined; the material is placed in an inclined chute and slides by gravity under the ram.

(d) Dial Feed. The work is carried under the descending ram by a revolving dial, fed by hand or by a gravity chute.

(e) Revolving Dies. Two or more dies are constructed on a plate, which revolves at each stroke of the ram. The operator places the work in an empty die; when the die plate revolves it carries the work under the ram.

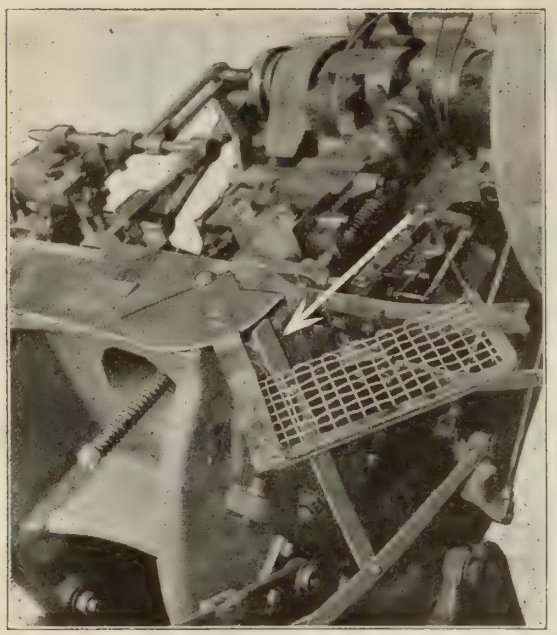
(f) Sliding Dies. Each operation slides the die from under ram. The operator loads the die, and with the down stroke the loaded diet slides back into position.

The principal hazards of an automatically fed machine occur when adjustments are being made, or when dies are being changed. If the plunger makes a stroke at such a time a serious injury may occur. Every such machine should be equipped with an automatic stop which will lock the machine whenever continuous operation is interrupted. The plunger and dies should be enclosed, if possible, to remove all danger of operator's hand being caught.

Blanking

In blanking operations, especially when hand-fed, the plunger should be enclosed at the front and both sides by a guard of wire mesh, perforated metal or wired glass, leaving just enough space under guard to admit the stock. If of a metal, the guard should contain a slot through which the operator can view his work. For hand feeding, this guard must fit the die closely; it should, therefore, be readjusted, or a separate guard provided, by the die maker or die setter whenever a new operation is put on the machine.

A telescope guard, attached to the ram,

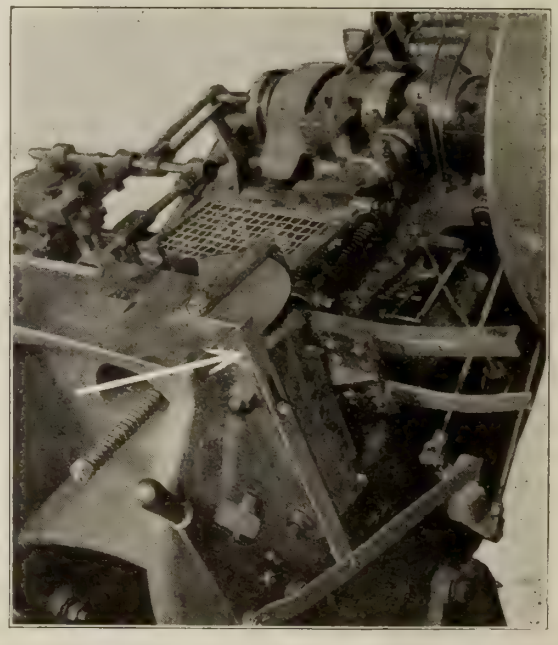


LOCKING DEVICE FOR CLUTCH OPERATING LEVER. NOTE THAT WITH GUARD OUT OF POSITION LEVER IS LOCKED SO THAT PRESS CANNOT BE STARTED.

CHUTE WITH DIAL FEED. MATERIAL IS CARRIED TOWARD THE DIES BY THE REVOLVING DISC.

GRAVITY CHUTE FEED.

AUTOMATIC PLUNGER FEED.



LOCKING DEVICE FOR CLUTCH OPERATINC LEVER. NOTE THAT THE GUARD IS LOCKED IN POSITION BL ROD CONNECTED TO OPERATING LEVER.

is sometimes used in place of a basket enclosure.

In large blanking operations, using long sheets of metal, the operator must ordinarily reach through the machine for the stock, unless a helper is stationed behind the machine. This hazard may be avoided, and the speed of operation increased, by the use of a vacuum pick-up controlled by the operator.

Many of the devices discussed under "Forming" may be used for blanking, but do not furnish as complete protection as a plunger enclosure.

Forming

For many forming operations an automatic feed can be devised and the plunger enclosed. With hand feeding, a fixed plunger enclosure is often impracticable. In such cases particular attention should be given to the design of dies, and in addition a device should be provided which will minimize the possibility of the operator's hand being left between dies. Each of the following types has its particular field of usefulness:

(a) A sweep bar or gate, which swings across or moves upward in front of dies, or moves across lower die, as the ram descends, and thus pushes hands out of danger. Such a guard should be operated by movement of ram, not by treadle.

(b) A swinging, sliding, dropping or expanding gate which forms a guard in front of dies before ram descends. This is operated by the treadle. If hand is in danger the gate cannot close and the treadle will not operate.

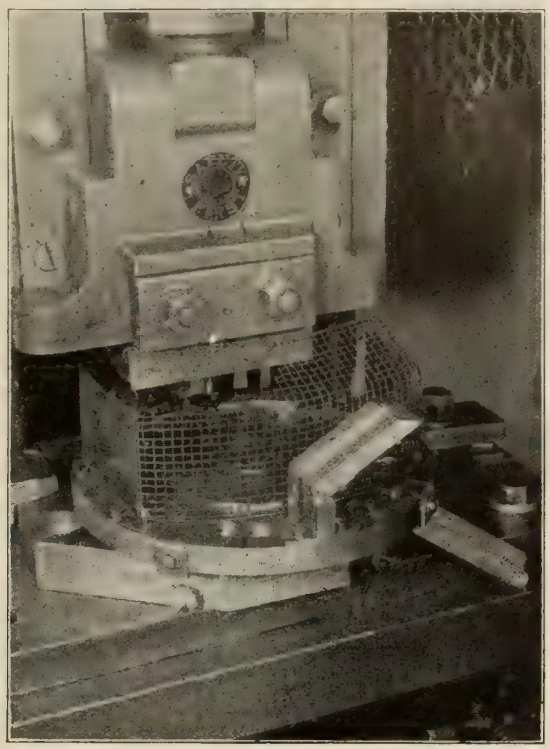
(c) A two-handed lever or push-button device which requires the use of both hands to trip the press or release the foot treadle. Where several men are employed at one large press, an electric control may be arranged with push-buttons in series, so each man must press two buttons (one with each hand) before the press will operate.

(d) Tell-tale device which warns the operator of descending ram if his hands are in danger zone. These are not positive in action because they do not remove the hands from between the dies.

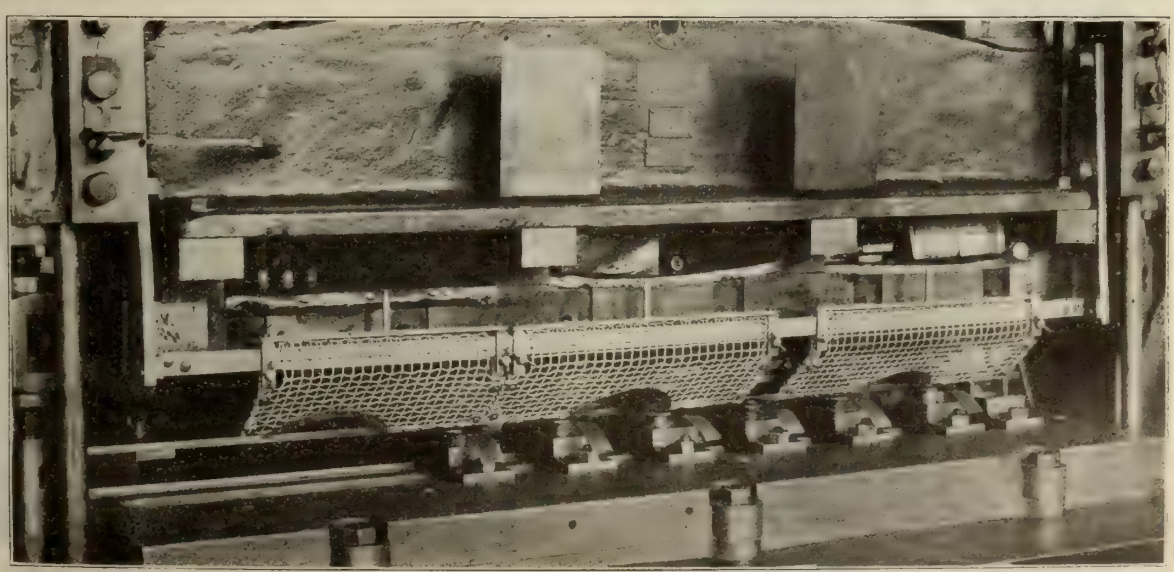
(e) Tweezers, picks, air suckers, or electro magnets, with which the material may be placed between the dies. The use of these hand-feeders frequently increases the output as well as decreasing the hazard.

Removing Stock From Press. Many accidents result from workmen's hands being caught while removing stock from press. In many operations the work is liable to adhere to the die, and a stripper or a kick-out device should be provided. A picker, or compressed air, may also be used to remove the work.

Blanking and forming are sometimes done in one stroke of the plunger; the cutting die blanks the piece and the forming die completes the operation. This double operation is often dangerous unless special methods are used to decrease the hazard.



REVOLVING DIES AND CHUTE FEED. PIECES ARE PLACED IN CHUTE, AND DROP INTO DIE, AND ARE CARRIED UNDER PLUNGER BY THE REVOLVING DIE PLATE. PIECES ARE DISCHARGED THROUGH CHUTE SHOWN BELOW PLATE.



GUARD FOR DIES FOR GANG PRESS.
Guards may be adjusted along length of supporting rod. Enough space is left for feeding material, but not enough for fingers to be placed under plungers.

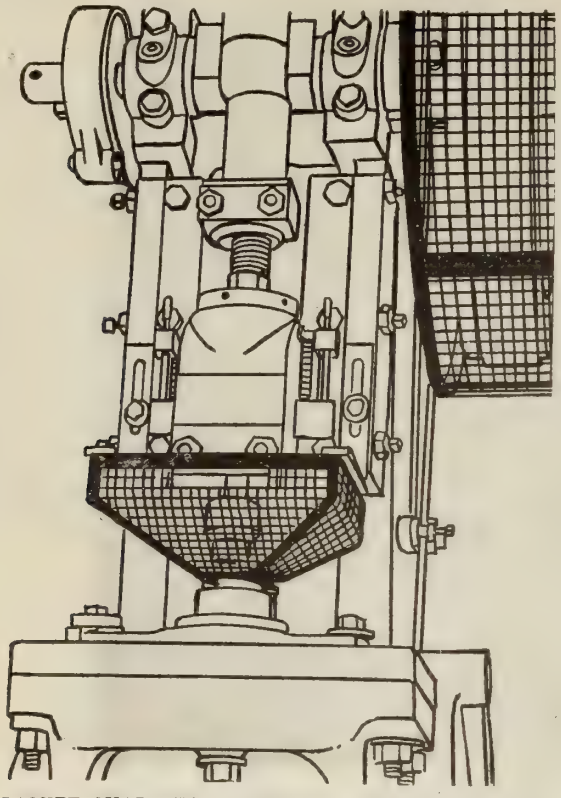
Discipline. Most of the safeguards described in paragraphs 10-12 can easily be put out of use by the operator, or can be wrongly adjusted so they will give

little or no protection. Such types of guards are valueless unless they are kept in proper adjustment and the use of them strictly enforced.

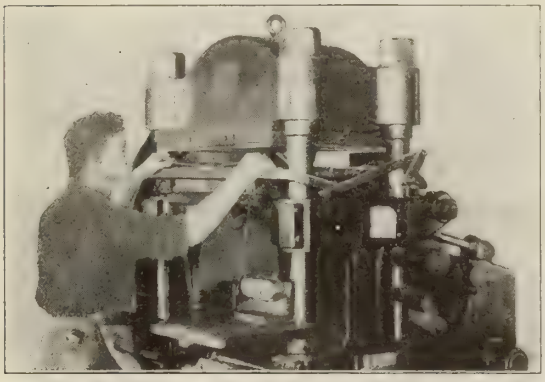
Die Making

The safeguarding of presses should begin with the design of the dies. As much study should be given to the safety of the operator as to the mechanical efficiency. Safety in press operation can only be secured by keeping the operator's hands out the danger zone. Although mechanical safeguards are designs for that purpose, practically all types of guards may be rendered ineffective by the operator or by error.

To be continued

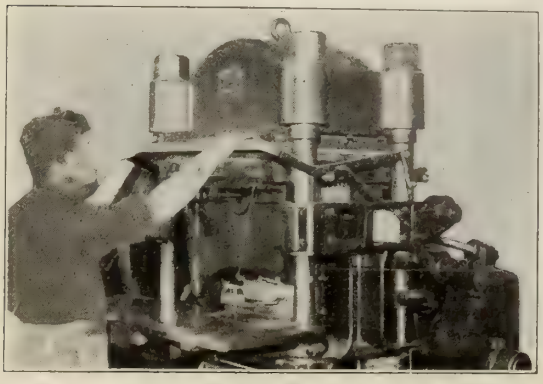


BASKET GUARD FOR BLANKING. FRONT AND BOTH SIDES ARE GUARDED. OPENING AT BOTTOM IS JUST LARGE ENOUGH FOR PLUNGER TO PASS THROUGH. THIS GUARD INCREASED PRODUCTION, SCRAP MATERIAL BEING USED.



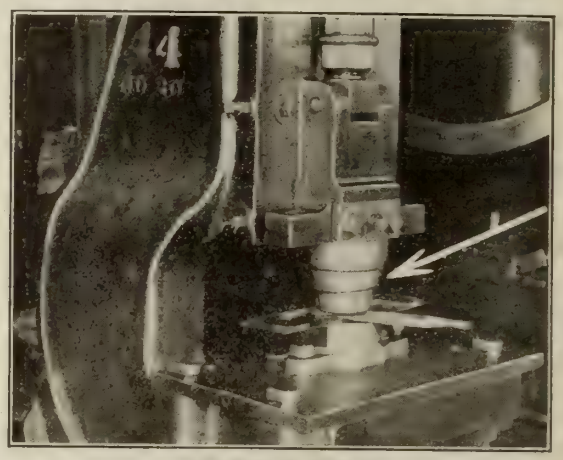
SAFEGUARD FOR STAMPING OR EMBOSSING PRESS.

Guard lies against platen and does not interfere with placing material in press.



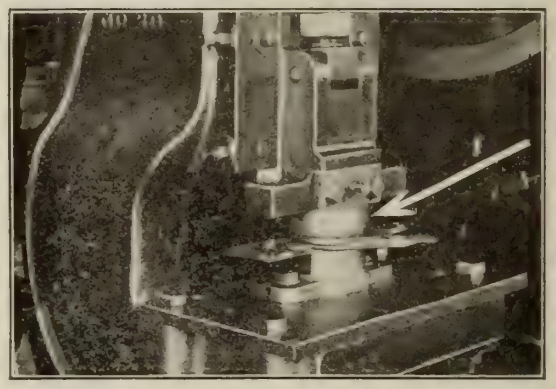
SAFEGUARD FOR STAMPING OR EMBOSSING PRESS

The upward stroke of platen, by means of two pins and a bell crank, pushes guard upward and outward, thus removing operator's hands from danger zone.

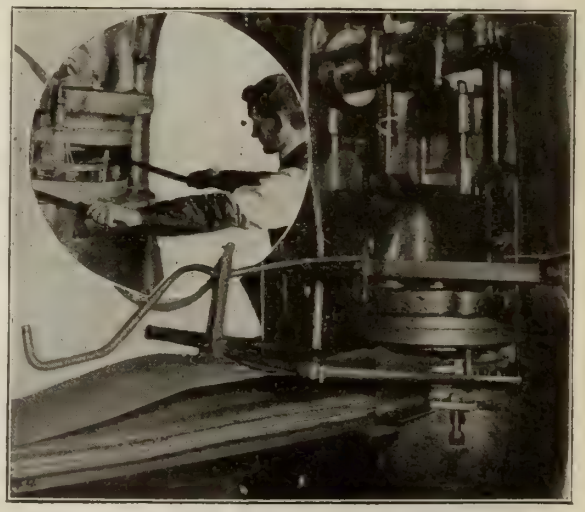


TELESCOPE GUARD.

This guard surrounds plunger and is fastened to head so that as ram descends the parts telescope one within another. At the top of stroke enough space is left for feeding stock, but not for getting fingers under guard.



TELESCOPE GUARD SHOWING RAM AT LOWEST POINT OF STROKE.



SUCTION DEVICE FOR FEEDING HEAVY SHEETS.

Operator at front of machine grasps the handles and pushes the device back on supporting rod until it comes in contact with top sheet of material. When lever controlling air valve (attached to handle) is pressed, the sucker picks up sheet and operator then pulls it toward him. (The large view shows rear of machine, with material in position for first punching.) Operator then grasps sheet by the front corners and continues to feed through machine. The use of this device has done away with need of a helper and has increased production.

Shop Arithmetic, Simple and Compound Levers

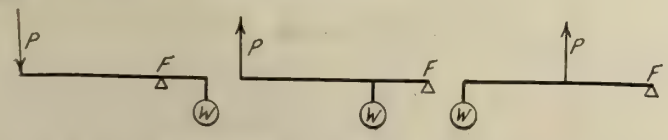
Tenth of a Series in Practical Mathematics for the Mechanic and Those Learning the Machinist Trade—Simple and Compound Levers Met in Every-Day Practice Are Discussed in This Issue

By J. H. RODGERS

IF the design and construction of machinery is traced back to its origin it will invariably be found that the elementary principle that predominates is that of the lever, in one or other of its many forms. A brief study of any piece of mechanism will readily prove this assertion. Two other fundamentals might be classed as primary factors—that is, the cord and the wedge—but these two latter are nearly always associated with that of the lever, and could well be considered incidental to the lever principle. The lever in its simplest form might be termed the pioneer machine, as man in his prehistoric state used the limb of a tree as a lever, to move the rock to and from the opening of his cave, to protect him from the perils of the outside world. In the present day the lever in itself retains all the theoretical advantages—no more or no less—that it did in the olden times, but the requirements of modern methods has compelled men to develop it to its highest state of efficiency, so that in many of the intricate mechanisms of to-day, the lever, as a common lever, has practically disappeared, especially to those unable or unwilling to observe the development of the evolution.

The lever is a bar or beam that is capable of turning about a fixed point that is called the fulcrum. The lever, commonly recognized as such, is a straight bar supported at the fulcrum, with the force applied at a relative distance from the weight and the fulcrum, so that the two former are in equilibrium. The principle, however, need not, and as a matter of fact, is not restricted to a straight bar, but may be applied in one of many forms, such as gears, pulleys and arms of any desired shape, but the underlying principles are never altered.

The three factors—apart from the lever itself—that constitute the practical application of the lever, are the fulcrum F, the power P, and the weight W; the position of the former to the latter determining their respective values and the classification of the lever. As there are three factors in the makeup, it follows that there will be three types of levers, and these are shown in the sketch below.



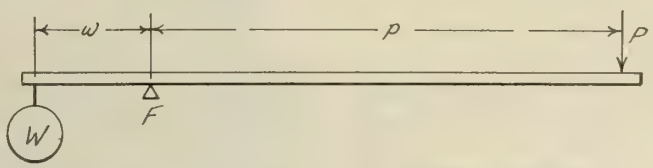
At A is shown the first form, where the fulcrum comes between the force applied and the weight supported. At B is shown the lever of the second form, where the weight is supported between the fulcrum and the force applied. The third form is shown at C, and here the power acts between the fulcrum and the weight. The classification—weight—that is generally given to any object, is the force of gravity or the attraction of the earth for that body. It is impossible to eliminate this natural force, and it is ever present in all substances, but by means of various devices, its action, apparently, may be suspended, only, however, to be transferred to another body, as the initial attraction still exists, being active through the other medium. For example, suppose a force of 100 lbs. at P, in the first form of lever, supports a weight of 100 lbs. at W; the weight is temporarily suspended, but the force of gravity still acts through the lever and the fulcrum, with the result that the downward pressure of 200 lbs. is exerted at the fulcrum F.

As stated above, the value of the power and the weight is dependent on their relative distance from the fulcrum. In working out problems involving the principle of the lever, the application of ratio and proportion is extensively used.

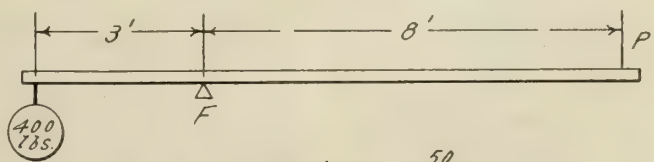
When a weight is supported on a beam or a lever, it always has a tendency to revolve about the point of support or fulcrum; this action is called the moment of the force and may be determined by multiplying the weight or force by the distance from the fulcrum. Equilibrium is attained when the force moment balances the weight moment. To lift a weight the power moment must be slightly in excess of the weight moment, but this need not be taken into account when calculating such problems in ordinary shop work.

The equation for all lever calculations may be stated as follows: Force multiplied by the force arm equals the weight multiplied by the weight arm. In the expression of a formula and using the letters as shown in the sketch, the equation would be:

$$P \times p = W \times w.$$

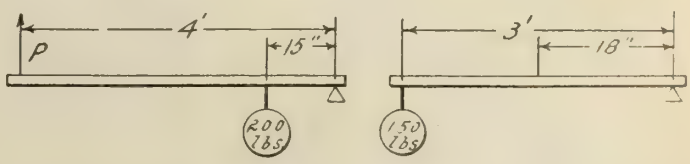


A concrete example of the above may be given. Suppose it is desired to support a weight of 400 lbs. at a distance of 3 feet from the fulcrum, and the power arm is 8 feet long, and on the opposite side of the fulcrum; what force would be required?



$$W \times w = P \times p \qquad P = \frac{W \times w}{p} = \frac{400 \times 3}{8} = 150 \text{ lbs}$$

The solution for the second form of lever is similar to the first, and the advantage is practically the same, the difference being that the force acts in the opposite direction to the weight—upwards. In the third form the action is the same as the second, but the mechanical advantage is lessened owing to the



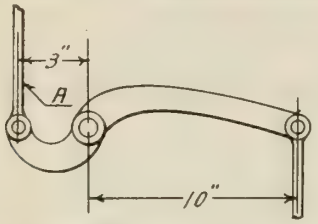
$$P = \frac{W \times w}{p} = \frac{200 \times 15}{4 \times 12} = \frac{125}{2} = 62\tfrac{1}{2} \text{ lbs.}$$

$$P = \frac{W \times w}{p} = \frac{150 \times 3 \times 12}{18} = 300 \text{ lbs}$$

fact that the power applied must be greater than the weight supported. Below are examples of the two latter forms of simple levers.

It will be seen from the above that, when the power acts between the weight and the fulcrum it must be greater than the weight; therefore, for general purposes, the efficiency of such an arrangement must necessarily be considerably less than the levers of the first and second orders.

In the examples that have just been given, only straight beams have been considered, but it is seldom that these ideal conditions will occur in practice, and in many instances it is not advisable that they should. The fundamental principles, however, are the same in every particular; and that is, that calculations for the different moments must be made on the 90 degree basis, where the arm length is taken as the perpendicular distance from the direction of the pull or force applied to the point of support. The principal objects of irregular shaped levers is to avoid interference with other parts of the mechanism when in motion; sometimes the shapes are designed for appearance only.



The above sketch shows a type of lever that is frequently met with in machinery, and in this particular case the primary factor is the movement of the ends to operate slides or valve spindles. In the example here given it is required to find the throw of an eccentric or the lift of a cam, operated on the long arm, to give a vertical movement of 1⅜ inches to the rod A. To the right is shown a skeleton drawing of the centre lines of the lever, and the arc passed through in making the cycle. To find, by calculation, the required throw, use the principle of proportion as explained in a previous lesson.

$$3 : 10 = 1\tfrac{3}{8} : X$$

$$X = \frac{10 \times 1\frac{3}{8}}{3} = \frac{\overset{5}{\cancel{10}} \times 11}{3 \times \underset{4}{\cancel{8}}} = \frac{55}{12} = 4{\cdot}58 \text{ in.}$$

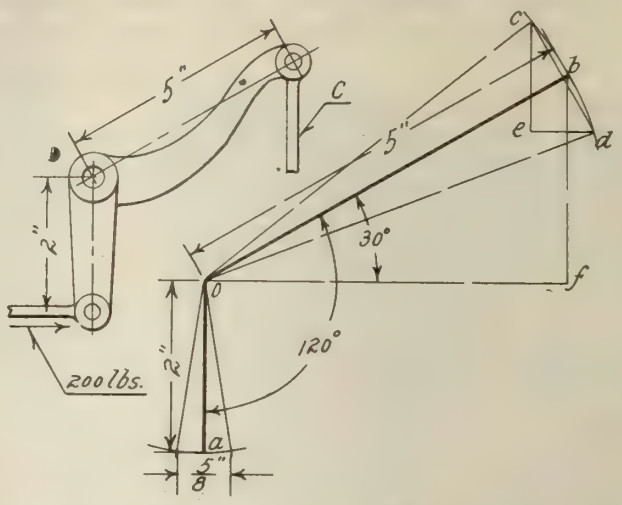
It often happens that a lever may be placed in a position that a direct right angle pull is impossible.

In the sketch shown the rod B is to have a movement of 5-8 of an inch, and is to overcome a resistance of 200 lbs. With the dimensions given, what will be the vertical movement of the rod C, and the force required to overcome the pressure acting at B? The length of the chord c-d, at the extremity of the long arm, can be found by proportion, thus:

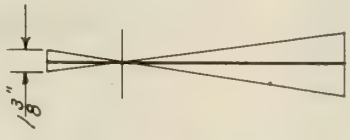
$$\tfrac{5}{8} : c\text{-}d = 2 : 5$$

$$c\text{-}d = \frac{\frac{5}{8} \times 5}{2} = \frac{5}{8} \times \frac{5}{2} = \frac{25}{16} = 1\tfrac{9}{16} \text{ inches.}$$

It will be seen, however, that the upper end of the vertical power rod C will travel through the arc c-b-d, but due to the inclination of the arm at the angle of 30 degrees to the horizontal, the



throw of the crank at the lower end of the rod C will only require to equal the length c-e of the right triangle c-e-d. This length may be found by "trig" and



the rule to apply would be: Side adjacent equals hypotenuse multiplied by cosine, or:

$$\text{Side Adj.} = \text{Hypot.} \times \cos. = c\text{-}e = (c\text{-}d) \times \cos. 30$$

$$c\text{-}e = 1\tfrac{9}{16} \times {\cdot}866 = 1{\cdot}353 \text{ inches.}$$

As b-f is the direction of the power pull the moment for the power arm must be found by multiplying the power applied by the length of the line o-f, perpendicular to the line b-f. This length can be determined by the formula:

$$\text{Side Adj.} = \text{Hypot.} \times \cos. = 5 \times {\cdot}866 = 4{\cdot}33 \text{ in.}$$

Then the power required to overcome the resistance of 200 lbs. at the short end of the bell crank would be:

$$2 : 4{\cdot}33 = X : 200 \quad \text{or}$$

$$X = \frac{2 \times 200}{4{\cdot}33} = \frac{400}{4{\cdot}33} = 92{\cdot}4 \text{ lbs.}$$

FORD-SMITH MILLING MACHINES

Unfortunately our composing room dept. made a rather peculiar error on page 10 in advertising section of our Aug. 7th issue.

This referred to the Ford-Smith Machine Co., Ltd., of Hamilton, Canada, who are well known for their line of milling machines.

The advertisement was made to read "Mining Machines" in place of "Milling Machines."

The corrected advertisement appears on page 74 of this issue.

The earliest known mention of cigars is in a book published in 1740 under the title of "Distresses and Adventures of John Cockburn." It appears that Cockburn was cast on a desert island in the Bay of Honduras, from which he swam to the mainland, and thence travelled afoot to Porto Bello, a distance of 2,600 miles. Here he met some friars, who gave him some "seegars" to smoke. "These," he says, "are some leaves of tobacco rolled up in some manner that serves both as pipe and the tobacco itself." Though this is the earliest date at which cigars appears to be mentioned by that name, so far back as 1498 two soldiers sent by Christopher Columbus to explore Cuba told their companions on their return how the natives carried in their mouths a lighted firebrand made from the leaves of a certain herb, rolled up in maize leaves. The description of an Indian method of smoking given by Lionel Wafer, in his "Travels in the Isthmus of Darien," in 1699, shows that they then smoked cigars made just as they are made now.

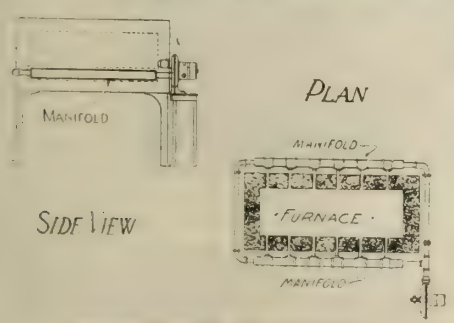
A Combination Gas or Electric Blow Torch

With an Improvised Furnace, of Ordinary Firebrick, You Can Produce the Same Results as With a High Temperature Furnace. That is—if You Use a Torch as Herein Described

By FRANK C. PERKINS

THE accompanying illustration, Fig. 1, and drawings, Figs. and 3, show the operation of a gas-electric blow-torch, developed at Cleveland, O. It is stated that with an improvised furnace of ordinary firebrick, using the gas-electric blow torch, one can produce the same results as with a high temperature furnace—and at only a fraction of the cost. It requires neither engine, compressor, nor any special alteration of equipment. It is self-contained, requiring only connection with the electric light socket and the gas line, to produce a clean, even temperature up to 2,500 degrees Fahrenheit.

It is pointed out that it takes only a minute to put the blow torch into operation as it is only necessary to turn on the current, light the gas, and it is ready. It is instantly adjusted to any position or angle, and it can be carried anywhere in one hand. The cost of operation is only from five to ten cents per hour, and the intense heat produces results in time and money saving almost beyond computation. There is practically no machine shop, blacksmith shop, automobile repair shop, welding shop, or factory where metals are used and heat is required that a gas-electric blow torch cannot be used to advantage. It is convenient, economical, and most satisfactory as a heating equipment for hardening (including high-speed steel), tempering, annealing, forging, brazing, making shrink fits, pre-heating for acetylene welding, babbitting, removing

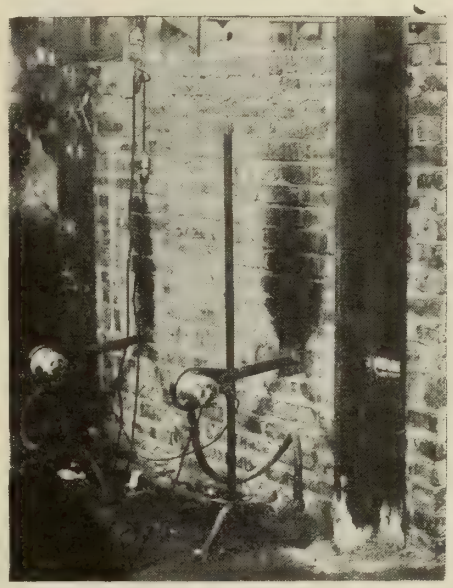


OTHER VIEWS OF FURNACE.

babbit from bearings, melting various metals, also for making pattern castings, straightening bars, shafts, frames, axles, crank shafts in centre, and bending tubing and heating rivets.

It is used to advantage for hard soldering, fitting boiler patches, skin drying, molds, heating core ovens, repairing tools, drying cores, repairing patterns gates, riveting frames, housings and spindles, also for removing old insulations from stators, armatures and soldering large commutators, removing pulleys.

It is claimed that one of these burners has been developed which is extremely useful for small soldering jobs—for brazing or for heating parts in inaccessible places, and it can be either attached to the regular burner or can be made extremely flexible by using the reducer,



ILLUSTRATING THE IDEA, AND INSTALLATION.

as illustrated, and a short length of hose. The maximum flame length is about 10 inches, the diameter 1½ inches at its largest point. The minimum flame length is three inches, with a diameter of one inch, tapered to a cone. The maximum gas consumption is 52 cubic feet per hour with natural gas, and 70 cubic feet per hour with artificial gas. The minimum gas consumption is 18 cubic feet per hour with natural gas and 25 cubic feet per hour with illuminating gas.

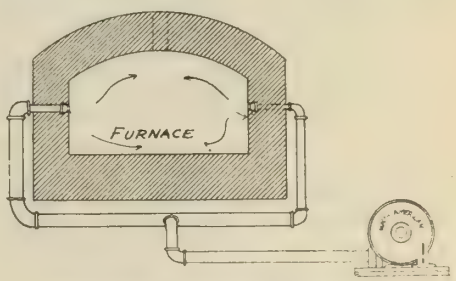
Another blow torch attachment has been designed which gives the same satisfactory results when used for small hardening or melting furnaces. The reason for using this attachment is to prevent the burning of the nozzle when it is inserted into the furnace. Gas is protected into the furnace and does not burn on end of nozzle. Changing from the blow torch to the furnace burner can be done in a moment by simply slipping the one off and the other on.

The oil-electric blow torch operates with the same high efficiency as the gas-electric torch, the only difference being its ability to burn kerosene. This oil-electric blow torch is fitted with a specially designed kerosene oil burner. This burner operates on the atomizing principle, but is also fitted with a vaporizing coil to gasify the fuel after the burner has been in operation long enough to heat the coil.

The particular feature of the oil-electric blow torch is that it will light instantly without pre-heating. It produces a clear luminous flame of approximately the same temperature as the gas-electric torch. Its range of control is excellent—furnishing a maximum flame length of about 24 inches with a diameter of 5 inches at its largest point.

The electric blow torch will also burn either natural or artificial gas successfully and is fitted with a gas control cock the same as the gas-electric. Thus this torch is really universal. It can be used in the city for the many heating and repairing jobs to which it is adaptable, and it can be easily transported to the country or to any district where there is no gas, and used with oil. The maximum kerosene oil consumption of the oil-electric blow torch is approximately 2½ gallons per hour—the minimum 1½ gallons per hour.

The gas-electric blow torch has a blower of extremely substantial construction, which will operate continuously for practically any length of time, due to the fact that over-heating of the motor is absolutely prevented by the air entering the blower which must first pass around the motor before entering the fan chamber. The gas enters through the opposite side, and the mixture of air and gas is made perfect by



SECTION THROUGH FURNACE.

the rapidly-revolving fan. When the mixture leaves the fan chamber it is a perfectly homogeneous mixture of air and gas of the most combustible nature. Both the volume of air entering the blower housing and the supply of gas is under instant control. The motor is entirely enclosed to prevent dirt or dust getting in contact with the bearings and other moving parts, and the constant cooling blast of air keeps it in perfect running condition.

The Various Mechanical Properties of Steel

Taking Up the Consideration of the Question of Brittleness, Together With Investigation of Failures of Various Kinds. A Paper of This Nature on Steel is Especially Valuable at the Present Time

By W. H. HATFIELD, D. Met. of the Brown-Firth Research Laboratory, Sheffield, Associate Member

(Continued from last issue)

IN a recent paper previously referred to, Rosenhain and Hanson describe an investigation into the cause of cracking in a thick boiler plate. The failure examined occurred in the last stage of manufacture, that is, cracking during cold bending. The authors present interesting data, and the results of subsidiary experiments bearing upon the case. They deduce that the cause of failure lay in the growth of large crystals in the ferritic bands, claiming such crystalline growth to be responsible for the low impact value of the material, and that the low impact value of the material was an indication of the mechanical properties which produced failure. The processes through which this particular plate had passed were those through which other plates had passed which had not cracked, and the author's conclusions would have been more convincing if they had definitely shown that successful plates had not possessed the same features which they condemned in the plate which had failed. One would rather suspect that the breakage of this plate was due to the presence of mechanical defects or the production of small incipient flaws by over-bending in the cold. Unfortunately, the stages of bending are not published. The author discusses this paper now, since it has a direct bearing upon the technical points which he hopes to bring forward later.

Another well-investigated failure is that of the St. Neots rail. This failure was the subject of a Board of Trade Inquiry. It has also been dealt with by Dr. Arnold, F.R.S.; Dr. Stead, F.R.S., and others. Here we have an extremely valuable instance of a failure with many well-authenticated details. The rail was 22 years old, and it had worn down 5-16 in. under traffic abrasion; it then subsequently smashed into a number of pieces, causing the well-known disaster. One eminent investigator states that thousands of rails of worse composition had served satisfactorily. The mechanical properties, as shown by the tensile tests, were good. One extremely important feature, however, seems to be that the upper surface of the rail consisted in many parts of a martensitic layer (layer of hardened steel). This layer contained thousands of hair cracks. Such a martensitic layer may conceivably have been produced by abnormal effect of the brakes, and such a layer would yield the minute cracks just described under subsequent usage. The main points that it is wished to record are:

1. The original satisfactory condition of the rail as proved by the satisfactory behaviour over 22 years.
2. Its mechanical condition.
3. The presence of surface cracks.

Leaving this case for the present it is proposed to describe an interesting case which recently came to the author for investigation. He was informed of a case in which a piece of structural steel (angle-iron) made from shell discard, had broken sharply in two with a blow from a 14-lb. hammer. The fracture is illustrated in Fig. 1, page . He was incidentally informed that this occurrence had raised grave doubts in the minds of the firm concerned with regard to the advisability of the extended use of such material. In due course the pieces came into his hands, and an investigation was entered into with considerable enthusiasm, as here indeed was apparently an instance of really brittle steel. In the first place the chemical composition of the material was determined, and it was immediately found that the steel was not shell discard but low-carbon structural steel. That discovery, in itself, as will be appreciated, was quite an important one when present circumstances are considered. The figures obtained in the analysis were as follows:

	Per Cent.
Carbon	0.09
Manganese	0.65
Silicon	0.017
Sulphur	0.038
Phosphorus	0.061
Tungsten	Nil
Chromium	Nil
Nickel	Nil
Vanadium	Nil
Titanium	Nil

Microsections were prepared and the microstructure of the steel studied. In Fig. 2 will be found a photograph of the unetched structure which gives an idea of the amount of non-metallic inclusions present. There is, of course, always more or less of this non-metallic matter in these structural steels, and its layout is always parallel to the direction of rolling; hence in this particular instance the inclusions were in path at right angles to the fracture. In Fig. 3 will be found the etched structure at 100 diameters and the amount of pearlite, together with the size of crystal, can be studied. In Fig. 4 will be found the microstructure of the material at 500 diameters, and this particular photomicrograph enables the condition of the pearlite to be examined. The author did not consider that the micro-examination brought out anything abnormal, but found that it confirmed the results of analysis.

The mechanical properties of the material were next studied in proximity to the fracture. The tensile values, includ-

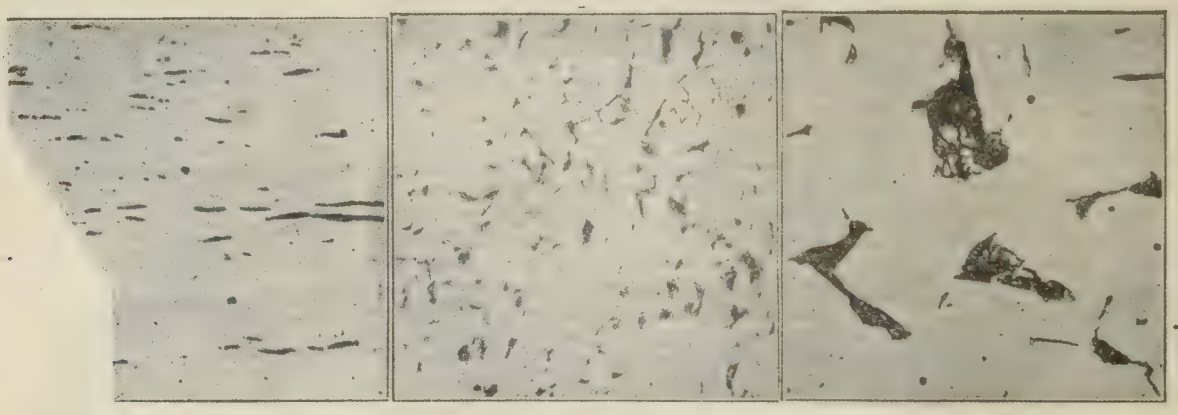


FIG. 2—UNETCHED x100 DIAM. FIG. 3—x 100 DIAM. ETCHED. FIG. 4—x 500 DIAM.

ing the elastic limit (limit of proportionality) were determined, and then the different values were obtained under the Arnold, Charpy, Izod, Fremont, Sankey, and Stanton tests. The hardness was determined by both the Brinell and Shore methods; the results will be found in the following table, whilst the full details of the actual tests will be found in Appendix I:

Tensile—	
Elastic limit	15.9
Yield-point	20.9
Maximum stress	29.4
Elongation of area	30.0
Reduction of area	61.9
Alternating Impact, etc.—	
Arnold alternating-stress test	211 reversals.
Charpy impac ttest	2.9 kgm. or 20 ft.-lb.
Izod	50 ft.-lb.
Frémont	23 kgm. 90 deg.
Sankey Alternating-bend test	33 bends 2,320 ft.-lb.
Stanton repeated-blow test	635
Harness—	
Brinell hardness number..	120
Shore Scleroscope number.	20.5

It is considered that these values are of much interest. In the first place, the Arnold and Sankey tests give too good values for the steel to be considered brittle. The Charpy, Izod, and Fremont gives values which must be considered very good, therefore the steel is not brittle under the notched-bar tests. For 28 tons to 32 tons steel the tensile values must be considered quite satisfactory. Why, therefore, should this angle-iron of good composition, microstructure, and mechanical tests break with a single blow from a 14-lb. hammer? The explanation appeared to be forthcoming as a result of a careful examination of the fracture. At the point marked by the arrow there was a discoloration indicating a sharp, already-existing crack of small area. The author considers that this crack led to an undue concentration of stress, and that, in spite of the good qualities of the material, fracture extended right through the piece in the manner described. Continued observations, both in this country and abroad, have readily and finally established that the sharpness of a notch or the gradually decreasing value of the radius at the bottom of the notch, accentuates its effect in reducing the amount of energy absorbed in destroying an impact test-piece. It is now firmly established that the stresses become increasingly great locally to a notch according to its sharpness. Professor Hopkinson, in one of his papers has observed quite truly that if the bottom of the notch or crack were infinitely sharp, this concentration of stress would cause the production by a small force of a high local stress at the base of a notch or crack sufficient to exceed the strength of the material and cause a continued propagation and development of fracture. In other words, failure such as occurred in this piece of structural steel, in some of the cases of boiler plate failures and, in the author's opinion, in the St. Neots rail, have been due to existing cracks of considerable "sharpness," which have, by their creation of unduly high local stress, exaggerated abnormally the work which the material was locally called upon to do. Impact values may vary considerably in a given steel, but a high impact steel as already shown, is not impervious to disastrous failure under conditions such as those just discussed.

It will be noted in the case of this piece of structural steel just described that the Stanton value is low. In a 60-tons tensile steel values of 6,000 to 8,000 blows are obtained. In this particular instance the energy of blow was exactly the same, and the low value is explained by the low elastic limit. It will be observed that this low value (Stanton) was obtained in spite of a high notched-test value. The general argument for the utility of the notched impact (single-blow) test usually relies on the claim that through inadvertence or design, sharp corners, notches, defects, even cracks have to be counted under actual service conditions.

Surveying notched-bar, impact and "fatigue" tests generally, the author considers that one definite fact is apparent, namely, fatigue tests with notches, such as the Stanton test, do not show any relationship to the impact values. For instance, two high-tension steels of a suitable elastic limit otherwise identical, one giving 50 ft.-lb. under the Izod, whilst another gives 8 ft.-lb., will be found not to show anw disparity under Stanton test, both breaking under that form of test at something like 7,000 blows. As an instance of actual observations made, the diagram shown in Fig. 5 is instructive. There will be found the results of tests on six 60 tons to 65 tons steels. The full tensile values, together with the Stanton, Izod and Charpy values were obtained. It is clear that everything else being equal, the incipient cracking prior to rupture of the material occurring at the notch of the Stanton test-piece should, on the above argument, have been prevented from developing by the high impact value of the material, thus providing a discrimination. To the author's mind it would appear that the inference to be drawn from this and other data which will be provided later, is that once the elastic range has been passed, final rupture cannot be prevented by variations in impact value. Hence arises the fundamental importance of thoroughly considering the distribution of stress and the providing of a sufficient factor of safety in relation to elastic range.

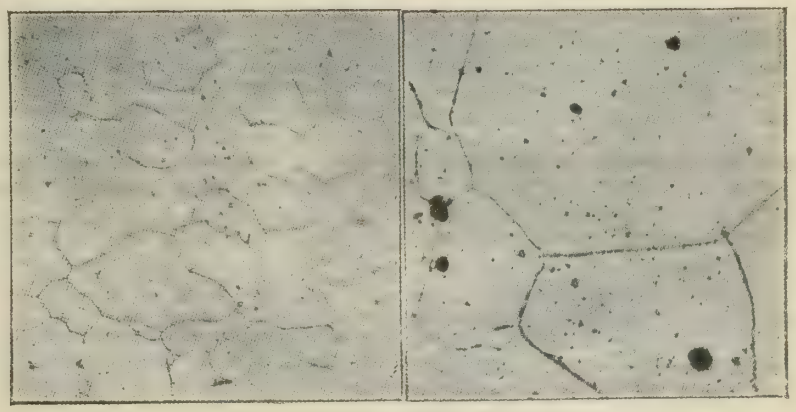

FIG. 6.—WROUGHT IRON AS RECEIVED x 100 DIAM. ETCHED x 500 DIAM.

A Discussion of the Methods Employed For Mechanical Testing

As regards the tests now in use for the mechanical testing of steels and irons, it may be safely said that each provides information of value. This may be stated without excepting any individual test. How are we to judge the relative value of the diverse means of testing from the engineers' point of view? It would appear that those tests are most instructive concerning the ultimate behaviour of the steel, which nearest approximate to, or reproduce, the conditions under which the steel has to serve. The tensile and torsion tests are of particular value, and in most cases clearly give a direct indication as to the suitability of the material. Particularly useful for purposes of design is a more complete knowledge of the elastic range under these two forms of test. Until more ready means of determining the limit of proportionality in the tensile test than the present-day extensometer can be obtained, such determinations cannot become routine tests, but the engineer might usefully obtain sufficient number of such readings to assist him in more accurately calculating his safe ranges of stress.

As regards the tensile test we have much to learn, and investigations such as those which have of late been pursued by Professor Dalby, F.R.S., are invaluable. He and other workers have advantageously shown the value of the detailed study of even our most commonly employed tests.

(To be continued)

In the slang of the United States, a "dago" is any dark-skinned foreigner from Southern Europe or Spanish America, especially an Italian, a Spaniard, or a Portuguese. In his "Life of Commodore Perry" (the American naval officer who opened Japan to commerce in 1852), Dr. William Eliot Griffis says: "In Spanish America 'Santiago,' 'San Diego,' 'Iago,' and 'Diego,' are such frequently recurring vocables that the Yankee sailors call natives of these countries 'Dago men,' or 'Diegos.'"

WHAT OUR READERS THINK AND DO

When is a Parting Tool Not a Parting Tool?

On July 17th We Published Mr. Ernest's Views on the Subject of Parting Tools. Here Are Two More, With Still More to Follow. Have You Sent in Your Idea Yet?

CUTTING-OFF IDEAS
Of S. G. Macklin

Regarding cutting-off tool discussion, I wish to continue where Mr. Ernest left off.

Having called your attention to the importance of a level bottom to the tool and proper side and end clearances, which have been well determined and can be obtained from any chart, let me suggest that the top rake and cutting edge can be made to suit various conditions.

The tool as made by the tool grinder is usually left level and square on the top.

Now, any tool which has been used a long time turning high carbon steel will have a little pit behind the cutting edge, proving that the flow of metal is decidedly tangent to the diameter. Now, this square cutting edge is on the same plane as a horizontal centre line, whereas the flow of metal being tangent must be so to a perpendicular one.

To accommodate this condition is the first consideration, for it is evident that the metal will pile up on the tool until there is sufficient pressure to compel it to change its direction of travel. The conclusion we have now reached being that we must grind a slight curve as our means of creating favorable conditions.

Observation of this one point will be the best guide.

We now have a tool that will offer the least resistance to the metal, and if we can insure the chip being of less width than the groove we wish it to pass out of, we can cut for months and not worry much.

When the metal meets the resistance of the tool there is as great a tendency to overcome this resistance sideways as endways. I mean that the chip has a natural tendency to spread.

We will grind our tool, not square across the end, but ever so slightly rounding. This gives the chip a natural tendency to curl its edges and make it narrower than the space cut.

It is this one thing more than any other that makes the difference between a good tool and another one on the same piece of stock.

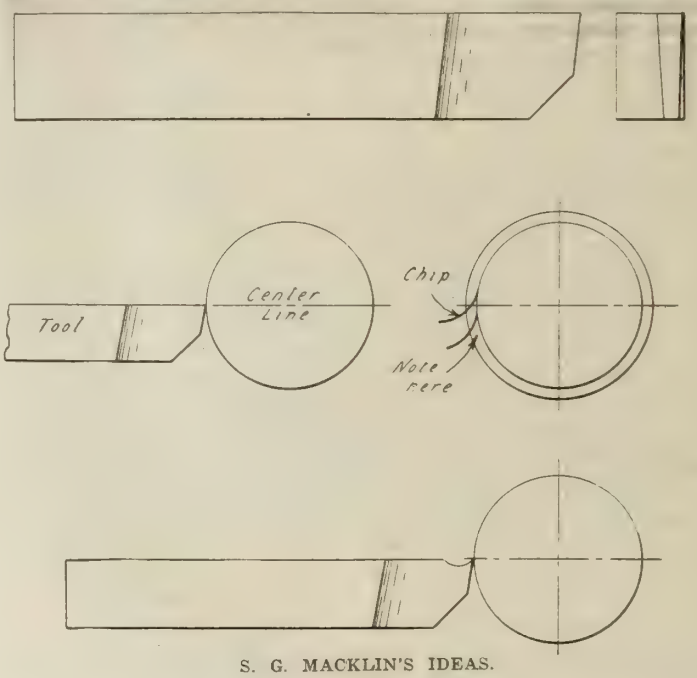
Many young fellows who think that cutting off stock is an art, that one has to be born with the know-how and so on, will realize that after many tries and careful grindings the cut-off tool got their goat, and with their patience all gone and a feeling of madness and despair, they grind again with a to-hell-with-it feeling, and the thing worked fine.

I offer this last as a suggestion that it is not the swearing that helps the job, but the ever so slightly rounding cutting edge.

The proof of these theories can be found in every-day practice.

If it is not so the metal on the sides of the cut will pinch and bind just as a board does on a rip saw.

But there are ways of using and keeping such a tool. The ideal cutting-off tool is the forged one with clearance below the top face and its clearance behind the point. Unfortunately this makes a weaker section where the stress is greatest. And workmen are prone to grind this forged tool on the top face, so that very soon it ceases to be the thing we so proudly forged, and gets shoved aside, the workmen meanwhile hunting for a better tool and growling about the "poor tools they have in this shop." It is difficult to reforge a tool so misused. The best way is to cut off the remaining part of the blade entirely and begin anew. The writer likes such forged tools and has been able to get the maximum of life from them when used personally, although the cost of the forged tool is almost as great as the inserted blade type, but prefers the latter style for all-round shop use.

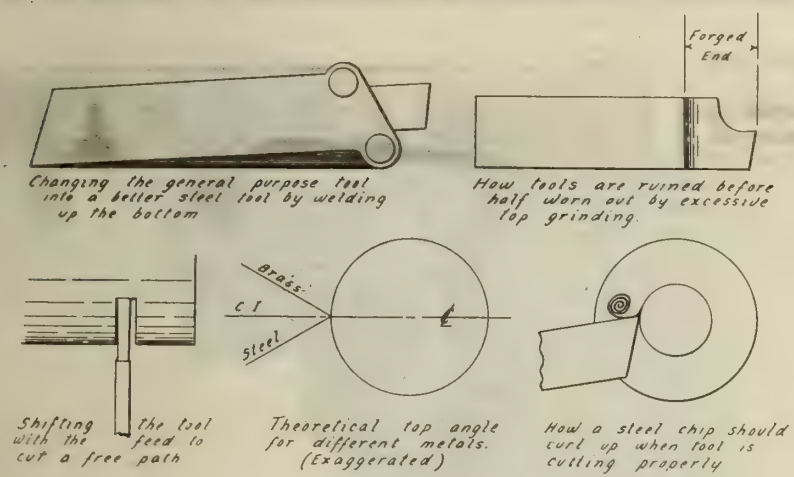


S. G. MACKLIN'S IDEAS.

CUTTING-OFF TOOL DISCUSSION
By Donald A. Hampson

The point that any cutting-off tool or parting tool must be wider at the extreme end than back of it is well taken.

A careful observer will have noticed that any tool cuts small when dull, and practically all tools will cut a path slightly in excess of their own width when sharp. So it is with the parting tool. If the edge is dull, ad particularly if the two corners get worn a bit, the tool will pinch and tear. More frequent touching on the front and less heavy grinding after it gets dull will be far better for the work. As it is hard to keep up the sharp corners in everyday hustle, some men grind them off into a 45 degree bevel of about a sixty-fourth in length. This seems to work well.



DONALD H. HAMPSON'S IDEAS.

Much of the work that is cut off has to be faced again or the end surface does not have to be particular anyway. A trick that will speed up this work remarkably is to cut a swath say a thirty-second wider than the tool by moving the carriage back and forth that much as the feeding-in takes place. This keeps a clearance on the tool at all times and permits a much higher rate of feeding. Moreover, the sides of the cut will look fully as good as the one where the tool got stuck and broke once or twice. This simple trick was passed along to the writer in Uncle Sam's country a number of years ago, by "a man from Canada," and it has been worth money to know it.

Many men make a mistake by overfeeding at the start. On a job of large diameter or a rough casting, they shove the tool in so hard or else have the lathe running so fast that the edge goes off on the first revolution. Thereafter they have trouble with the tool and consider themselves lucky if they get through the piece without a break. If the scale had first been ground off or cut away with another tool the cut would have been started correctly and under no handicap. A slower speed with patience is usually the "make haste slowly" of cutting off.

With tools of the Armstrong variety, the forging expense is entirely avoided and a well-shaped tool provided at the start. Mr. Ernest's trick of swelling the end of the blade to make a wider cut is good but the writer has seldon seen blades soft enough to do this. It will be found, however, that the necessary clearance is provided in most cases by keeping a sharp front edge and by cleaning the sides of the blade of the scale and black from hardening. Another advantage of this kind of tool is that almost any poor fist of a workman can sharpen it.

Poorly fitted and badly worn surfaces on the lathe are a source of trouble, but a free-cutting tool will make them less troublesome. Oil or compound of steel should be applied so it reaches the cutting edge; a drop there is better than a can spilled over the lathe, and then with a sharp tool, properly set, the chips will curl out with that peculiar hiss so welcome to the machinist.

Causes of tool breakage, other than already mentioned, are too much clearance on the front of the tool (which takes away the bearing and allows the tool to feed in too easily and too fast) and lack of rake on the top surface (which makes the tool grind and push the metal off instead of shearing it). True, the top of the tool may be ground at an angle forming a "lip," but as mentioned with the forged tool, this soon makes a great deal more grinding necessary or the reshaping of the tool.

The writer has bettered the standard tool holders in this respect by welding up the bottom full from heel to the screw boss. By so doing the blade is permanently fixed at an angle of about 7 deg. and an improved cutter for steel is thus arranged. It works well on cast iron, too.

Before hardening forged tools they should be set up on a planed surface and checked for clearance from the top down. If they don't show up correct in such a test with a square they should be ground or cut off in the shaper until they do. And a test for decreasing thickness back of the point should be made. It is often easier to correct defects here by filing than to do it with the wheel after the tool is hard.

A good way to ease up on the cutting-off tool on deep work follows. Suppose the cut is 2 in. deep; then, instead of setting the blade out two inches from the holder set it only one inch and cut that much with the stronger, stiffer tool. Set the tool out another half inch and cut that far. Finally cut the last half inch only with the weak tool.

Very often a parting tool is used full depth on a job that has a portion of the cut turned away afterwards. A better way is to do the other work first (as for instance, chamfering the heads of two bolts made together) and then cut off with the blade through the short section, avoiding the long cut and the tendency to rub on the sides.

Much of the trouble with such tools comes from not being properly set. They must be set with sides parallel to the cross feed or with equal side clearance to prevent crowding to one side with the attending crocked cut and broken blade.

Eggs are reported to be selling in some Russian cities at the equivalent of $5.10 apiece in currency. Russian currency is made by the process of running slips of paper through a printing machine. A good egg should be worth a lot of it.

After a survey of conditions the country over, the National Industrial Conference Board announced that the cost of living for American wage earners was 71 per cent. higher in July, 1919, than at the outbreak of the world war in July, 1914. This was said to represent an advance of 6 per cent. since March, 1919, and of 12 per cent. since June, 1918. The increase of 71 per cent since July, 1914, compared with an increase of 61.3 per cent. up to March, 1919, of 65.9 per cent. up to November, 1918, and of 52.3 per cent. up to June, 1918. The total increase for the five years' period on food was 85 per cent.; shelter, 28 per cent.; clothing, 100 per cent.; fuel, heat and light, 57 per cent.

For hundreds of years Mexican Indians had a horror of what they called the pest spot of Lake Chapala, near the shore at Tizapan, say the "New York Evening Post." They would not bathe in it or sail around it, declaring that the water was oily. Then, after a time, they cautiously began to paint their wooden boats with this oil, which proved so effective in keeping out the water that it became the general custom to use it. They did not know that this was petroleum gushing up through the water—a magnificent flow, about two miles out in the lake, which to this day gushes apparently without varying. When the water is low, petroleum floats in solid masses, each large globule weighing about twenty-five pounds.

Paris fashion reports tell of dresses in kid such as gloves are made of, and of trimmings of kid and patent leather on all sorts of outer garments. Leather being so scarce in Europe that boots and shoes have reached unprecedentedly high prices, it is to be requisitioned for other articles of dress also. That is the way of fashions. When leather is very plentiful again it will vanish from the costumes, and cloth-topped boots and whole cloth shoes will be in favor. It is a paradox.

DEVELOPMENTS IN SHOP EQUIPMENT

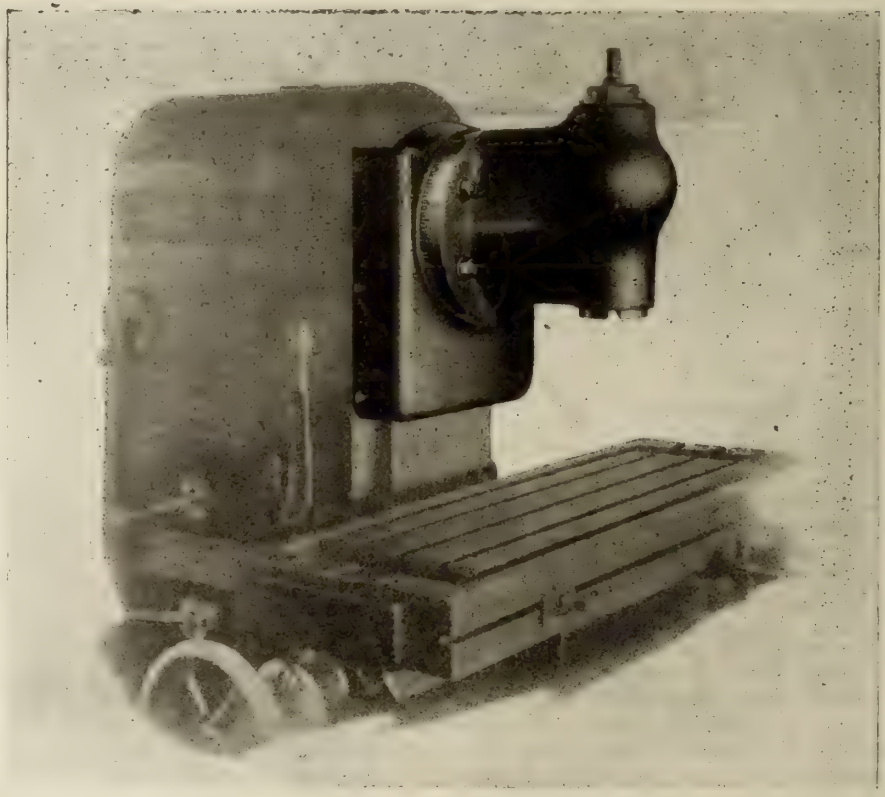
VERTICAL SPINDLE MILLING ATTACHMENT

Every machine shop at sometime or other has work that can be more advantageously performed with a face mill on a vertical spindle. To meet the demand of those who cannot keep a vertical milling machine busy, theere is always the vertical spindle attachment, which will give the range of a vertical milling machine on ordinary classes of vertical milling work.

The Cleveland Milling Machine Co., of Cleveland, Ohio, have developed a fixture of this nature, and a glance at the illustration will serve to show its general construction.

This attachment is of very rigid construction and capable of milling up to the capacity of the machine and is easily mounted on the face of the column.

The drive is taken from a gear fastened to the nose of the spindle, which in turn drives the spur gear on the horizontal shaft and the spindle is in turn driven by large mitre gears. All gears and shafts are made of steel and enclosed, running in bronze bearings throughout. The bearings on the spindle are the same as the milling machine spindle and form two taper cones in opposite directions adjusted by a nut on the outside of the spindle. The base of the head is graduated so that it may be set at any angle in a vertical plane parallel with the elevating screw. The distance from the face of the column to the vertical spindle and the distance from the nose of the spindle to the top of the table in the highest and lowest position covers the range of the ordinary vertical spindle milling machine. This attachment, when clamped in position on the dovetail slide of the column which extends above the centre line of the spindle, is as rigid as if it were a part of the milling machine.



CLOSE UP VIEW OF THE ATTACHMENT.

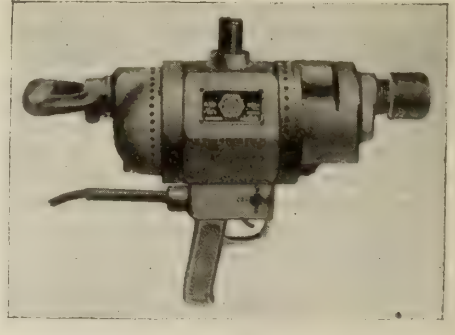
BLACK & DECKER ELECTRIC DRILL

The Black and Decker Manufacturing Company, 105-115 South Calvert St., Baltimore, Md., has recently added a new size to its line of portable electric drills. The new machine is shown in the illustration, and has a capacity up to 9-16 in. in steel, and is provided with a No. 1 Morse taper socket. It is stated the machine will drill a 9-16-in. hole through machine steel at rate of 1½ in. per min. without overloading the motor. The housing is of Magnalite, an aluminum alloy. The gears are packed in grease in a separate grease-tight compartment, and the drill spindle runs in a long bronze bushing, thrust being taken by a ball-thrust bearing. The motor is air cooled and will run continuously without overheating. The Morse taper socket is in the form of a separable sleeve secured in the drill spindle by means of a large knurled nut. By unscrewing this nut the entire taper socket is easily removed from the spindle. The drill shank protrudes slightly beyond the end of the taper socket, in order that the drill may be removed. This construction is used, for if it was necessary to leave room for the drift-pin slot the machine would be considerably less compact, and the end of the spindle would be some distance from the bearing. The machine has the customary pistol grip and trigger switch, which characterize Black & Decker drills. The machine weighs 21 lb., has a no-load

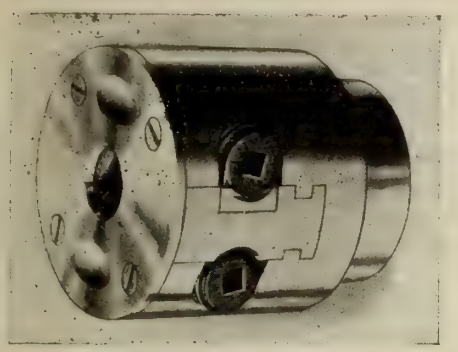


GENERAL VIEW OF DRILL.

speed of 600 r.p.m. and is supplied with interchangeable spade handle and breastplate, as well as electric connecting cable.

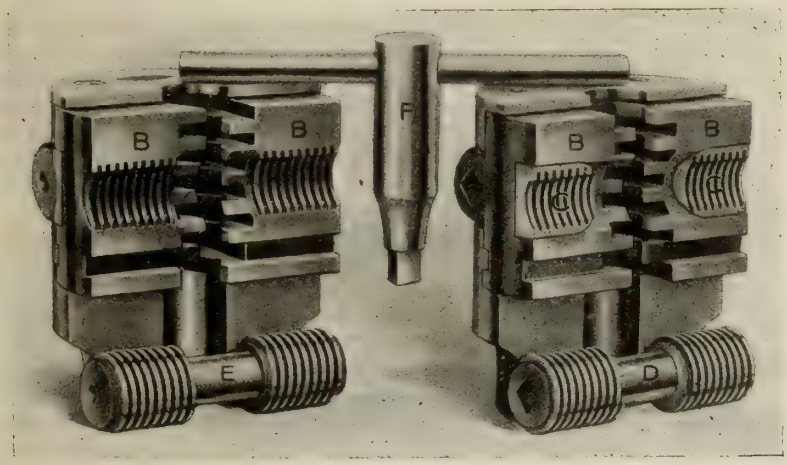
MARVIN & CASLER DRILL CHUCK

In the accompanying illustarations is shown the Casler twin screw drill chuck, which is a recent product of the Marvin & Casler Co., Canastota, N.Y.



GENERAL VIEW OF THE CHUCK.

The body of this chuck is made of close-grained cast iron, and jaws and screws are of tempered high-carbon steel. The claim is made that the combination of cast iron and steel gives long life to the wearing surfaces between the body, jaws, and screws. It will be seen that the body is reinforced by a steel cap plate, which prevents it from spreading when under strain; and a secondary screw doubles the grip of the drill chuck jaws and allows the drill to be driven to the limit of its strength. When using the chuck, the primary screw E, Fig. 2, is first operated to grip the drill shank between the jaws, and after this primary screw has been set up, the secondary screw D is operated to bring the floating nuts C against the ends of the pockets in the jaws B. The tightening of this secondary screw D results in producing a grip on the drill shank that is claimed to be twice as great as that obtained from a single screw. All parts of the chuck are made interchangeable to facilitate replacement, and there are no projections likely to catch the work or injure the operator.



SECTION THROUGH THE CHUCK.

NEWTON CENTERING MACHINE

The newly designed centering machine, illustrated and described herewith, is a recent development of the Newton Machine Tool Works, Philadelphia, U.S.A., for centering rough and irregular forgings.

Two universal centering vises of the interlocking type are supplied with the machine. The jaws are adjustable by means of a screw giving a capacity for rounds from 2 in. to 12 in. in diameter and of any desired length.

Vices are adjustable on the bed by means of rack and pinion.

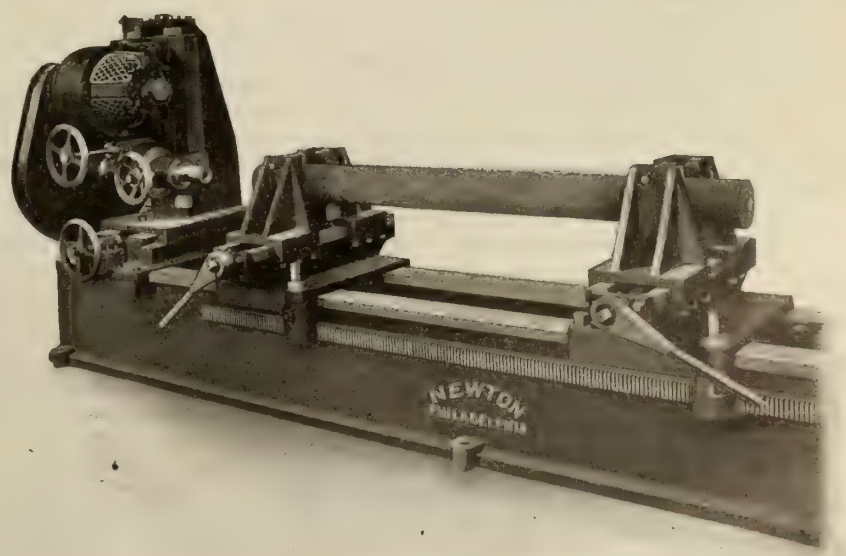
The spindle is of forged steel, 3 in. in diameter, running in bronze bushed bearings, has 4 in. cross and 4 in. of vertical adjustment, with 8 in. of hand feed.

The cross and vertical adjustments are equally divided from centre line of work.

The drive is by direct connected motor through a bronze driving gear.

Alignment of all adjustable parts is maintained by adjustable taper shoes.

Table of dimensions: diameter of spindle, 3 in.; in-and-out adjustment of spindle, 8 in.; vertical adjustment to spindle, 4 in.; cross adjustment to spindle, 1 in.; length of base, 16 ft.; width of base, 22 in.; distance centre of vise to top of base, 15½ in.; maximum distance centre of spindle to top of base, 17½ in.; minimum distance centre to spindle to top of base, 13½ in.



GENERAL VIEW OF THE MACHINE.

The All-Way Oiler Manufacturing Co., of Toronto, have placed on the market various oiler devices well worthy of investigation. The All-Way oiler is applicable to oil guns, combination filler and funnel, and the All-Way oil can.

Briefly, the oiler is the regular type of can fitted with flexible steel spout, made to bend in any desired angle or position without breaking or interfering with the flowing of the oil. There is no waste of oil when using this type of oiler, as the spout always reaches the desired spot.

At the end of spout a cleaning device is installed, which merely takes a second to operate. This same device also prevents oil from flowing too freely, thereby wasting.

The complete oiler is strongly made of copper-plated steel in different sizes.

Mr. H. Obee is manager of this concern handling these very useful lines.

Returns prepared at Washington indicate that stocks of food in storage in the United States on June 1 last were 20 per cent. greater than a year before, and the prices, where not higher than in 1918, were quite as high. There may be a suggestion of relief in such a situation, even if the profiteer is doing his best to prevent it. It costs money to keep foodstuffs in store, and the holder, if he does not sell, has to provide it.

One way to save time and eye strain is to prepare a large chart in the form of a stenciled board. This is made large enough for figures to be easily read from any part of the stock-room.

The Canadian National Exhibition

BEFORE the publication of next week's CANADIAN MACHINERY the Canadian National Exhibition will be in full swing. The last five occasions of this great fair have been held with the shadow of war hovering over, but they have achieved a great measure of success. This year, with the doubts and uncertainties of the war period put behind, it should surpass any previous attempt in both the number of its visitors and the excellence of the exhibits. Apart from the exhibits themselves, there will be much of a spectacular nature, to attract the seeker after fresh sensations. The presence of the popular son of our democratic King will also lend a fillip to the fair.

One of the finest features of this annual gathering is the opportunity it gives for Canadians to become acquainted with each other, and to learn the good points of parts of our broad country of which he has but the most vague ideas. There are many good people in Ontario who can expatiate largely on the wonderful mineral resources of their native province, who express extreme surprise when they are informed that Quebec produced the largest part of the world's asbestos supply. The man from the Western coast, who is apt to look on anything east of the Great Lakes as hopelessly slow and out-of-date, may feel like revising his opinion after a few days spent at the "Ex." Anything that can help to overcome the narrow sectionalism that is the bane of this country is doing a valuable work.

Paying for the War

THE aftermath of Great Britain's long struggle is reflected in the speech of Mr. Lloyd George, warning his countrymen of the necessity of buckling down to earnest work to pay their debts. Great Britain poured out her blood and treasure with a lavish hand, and gave of what was her most vital asset unsparingly, that is her superb merchant fleet. Although the returns for the quarter ending June 30th show that she is beginning to pick up in this direction, she is still a long way behind, and the production of the coal mines has fallen off lamentably. With more men than ever before employed in the mines, the short hours and higher wages have increased the production cost enormously. The attitude of the labor unions under these circumstances is hard to understand. What benefit will accrue to them if they kick the country into bankruptcy is difficult to imagine, and we cannot think that the sound common-sense of the British people will allow the warning to go unheeded. There is a lesson to be gained from the British situation that should not be lost on some of the malcontents in Canada.

THE COUNTRY will sympathize with Sir Robert Borden in his unfortunate accident, which compels him to remain in bed while the festivities are in progress. However, it might be worse. In days gone by, a slip by a public man on the steps of a club when leaving would have given rise to many unkind conjectures.

DR. R. J. McFALL must be trying to get a position abroad. He has now got up and said right out that the price of beef has dropped. To call attention like that to a thing that nobody had even noticed, is sure to get him disliked. We expect to hear shortly that he has received an appointment to investigate the clothing situa- in the Solomon Islands.

As a fundamental thing it might be well to say that labor should practise as well as preach. That is, take the same attitude towards capital that it asks capital to assume towards labor, live up to its agreements with capital, and be responsible for its acts.

"Scientific management" does not mean giving the smallest possible wage and selling the product in the dearest market—it means the greatest possible output with the least possible expenditure.

There is no doubt that there would be room for still further reductions in hours, and for considerable improvements in both time and piece rates, if we could as a nation accept the theory that when we are at work we should work with all our might.

The prospect for a broader development of the chrome iron deposits of the Eastern Townships is one of considerable interest to Canada as the deposits are quite extensive and have not been worked to advantage for many years.

Prior to the war these were worked by open cuts or quarries but the process became expensive and dangerous as operations descended to considerable depths and had to be abandoned owing to the low market price for the commodity. The big deposits which have served the big steel producing centres of the world are in Rhodesia and New South Wales, so that during the war the commodity advanced to a high price around $32 per ton.

SOME critics in England consider the money grants to the successful military and naval leaders as rather niggardly, if anything. Well, what does a half million pounds or so amount to in these days, when wealth is computed in billions?

Another Viewpoint on the Accident Question

By ALBERT HEPWORTH

In your August 7th issue of CANADIAN MACHINERY you print a short article by Master Mechanic on the needlessness of accidents.

Master Mechanic treats this as a matter that is up to the individual workman. So it is, BUT legislation for the protection of the employee is to-day making big strides, and while individual carelessness is responsible for most accidents the law seems to hold the employer responsible because, theoretically, he should see that there was no opportunity for carelessness.

This attitude is rather hard, but it has ended those little shops where five machines were crowded in where only two should have been, where a tall man had to be careful in straightening up for fear of hitting his head against the countershaft, or where one had to bend under the belting should one wish to leave his machine. The writer has worked in some of these machine shops.

Some accidents are no doubt hard to avoid. A man might suddenly be taken ill and so become caught in a machine despite guards, an emery wheel might burst when put in motion, and a piece escape from the guard with enough velocity to inflict serious injury, a shaft hanger may snap under some sudden tension and come crashing down, a punch press may repeat, etc. The first of these is so rare as to be nil; the second can be reduced to nil by careful instruction of the operator, so that he will handle the wheels as they should be handled and not thrown around every time they are changed; the third can best be eliminated by the use of a steel hanger, as this hanger will bend rather than break, and the fourth can be reduced to a minmum by careful and forceful instructions to both the die setter and operator, etc.

Accidents described under your sub-heading, "Don't Take the Short Cut," are simply up to the management, because the first rule of all safety-first campaigners in any shop is that safety first rules and regulations are to be enforced regardless of the prejudices or the position of the objectors.

The writer a few years back was employed in a press shop, where methods of production were rather loose. Of course, the rate of accidents was high. The introduction of state insurance quickly brought the state inspectors on the back of the officials, because of the high accident rate, and something had to be done.

It was pointed out that large concerns having special departments for employment adopted a physical examination, and it was decided to adopt this; and eventually discharge all those not up to standard. I, though in charge of a department, was automatically in line for discharge and it gagged.

Noting that the slackness over the shop was the same I had eliminated in my department, I took the bull by the horns and saw the manager, and in the end the promise was given me to have my views laid before the executive board. This led to the appointment of myself to the following new duties: (1) That all applicants for a job be subjected to a physical examination and the jobs graded, for it was felt that, whereas a physically perfect man ought to be less liable to cause an accident, this did not at all hold in practice, in fact, the reverse seemed to hold; (2) that a perpetual shop inventory be held and kept up; this eliminated a great waste, and in the case of piece-workers a great deal of intentional or unintentional over-counting; (3) that all safety guards be put up and kept up, I being responsible to see that they were; (4) that all employees were instructed in the methods of safety.

The plan of combining these duties was, of course, only feasible in a small shop, but it has been found not only there, but in larger shops that the making of one man responsible for the application of safety devices has tended to decrease accident.

In the above case we found that during six months this system was in operation (I left to take another position then) not an accident occurred, and as far as I know this still holds good, though I have been out of touch with this plant.

Accidents, like the poor, we have always with us, but they can be reduced to a disappearing point.

The State and Government Insurance Departments will hold the employer rather than the employee responsible; in fact, accusations of gross negligence or carelessness on the part of the workman, unless proven beyond dispute, will not exonerate. Elimination of accidents is up to the employer to a great extent. This does not mean increased cost, but will certainly mean higher production and more contented men. The employer who insists on safety first may in many cases be called a crank, but his shop will not be called a butcher shop.

The above, I hope, will give you some light on accident prevention, and I hope will answer in part the question contained in the last paragraph of the article by Master Mechanic.

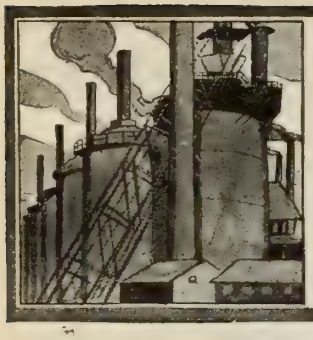
Dissolve one part of pearl ash in about eight parts of water; add one part of shellac and heat the entire mixture up to the boiling point. When the shellac has completely dissolved, cool the solution, and saturate it with chlorine until the shellac precipitates out entirely. When it is redissolved in alcohol, it makes a varnish which is as transparent as any copel varnish, and more satisfactory for a large number of purposes. This is a trade secret worth knowing.

To conserve the fats contained in the table refuse and dishwater of the soldiers' mess, the British military authorities installed grease traps. The fat collected in these traps averages more than one ounce for each man daily. The trap consists of a tin-lined wooden box, divided into two compartments by a partition that does not reach the bottom by about four inches. The dishwater and the table refuse are poured through a strainer into the vat. As the water cools, the fat forms a crust on top and is skimmed off.

A friend of mine who does heavy work of various kinds which requires gloves, and heavy leather gloves at that, advises me that gloves can be made to wear almost like iron by applying axle grease sparingly and being very careful not to get it on the cloth stitching, as the axle grease may disintegrate it somewhat.

Valuable china may be mended with the following mixture, and when dry it will resist hot water and ordinary usage. Mix a teaspoonful of alum and a tablespoonful of water. Place in a hot oven until it is quite transparent. Wash the broken pieces in hot water, dry and put them into the oven until they are warm; and while still warm coat the broken edges with the mixture thinly and quickly as it sticks instantly.

A handy paint mixer has recently been patented, consisting of a handle to which are secured two metal blades, intersecting each other at right angles. The lower portion of each is of dovetail shape, while above it is a pair of wings. This device is operated by immersing the blades in the paint, and then revolving them rapidly by placing the handle between the palms of the hands and moving them back and forth, as if rubbing them together.



MARKET DEVELOPMENTS

Dealers Report Continued Steady Buying

Machine Tool Dealers, Machine Shop Supply Men, and Steel Warehousemen All Report Steady Buying in Small Quantities—Automobile Trade Good Buyer

IN SPITE of embargoes, railway shopmen's strikes, and other strikes and threats of strikes, machine tool dealers, machine shop supply men and steel warehouse men profess themselves well satisfied with the situation. One machine shop supply man stated that the last two weeks were the best he had had this year, although all his business was made up of small orders. This shows that most of the small machine shops are keeping busy. An outstanding feature is the steady demand for material from the automobile trade, while railways are also buying freely, as reported last week.

* * * *

REPORTS from the United States show that there is a general stiffening of prices in the iron and steel markets. This is chiefly due to a better demand, but threats of further tie-ups due to various strikes make producers inclined to be conservative. There are so many factors to be taken into account that it is hard to keep track of them. The strike of the ore dockers stopped the movement of ore from Lake Superior, and the railroad car shop workers' strike produced a shortage of cars. Increased wages to railroad workers will bring about higher freights, so it is only natural that producers want to see just where they are heading. Basic pig iron has been sold in England at 165 shillings, considerably lower than American iron could be delivered there. There is considerable enquiry for export iron and the lowering of freights to Great Britain has enabled some orders to be booked for there.

* * * *

STEEL scrap has weakened somewhat from last week's prices, but it is thought that this is but a temporary condition. The labor situation is again affecting buyers of this trade, and the conditions are generally unsettled.

THE MARKET IS DULL AND UNSTEADY

Special to CANADIAN MACHINERY.

MONTREAL, Que., Aug. 18.—A combination of circumstances exist at present to make the current market of uncertain character. To the middle summer season, which is invariably associated with a decline in industrial activity and reduced demand, is added the disturbing element of labor unrest, a factor that is influencing the market conditions to no small degree. Conservative methods are the rule when sales are made, as the future is more or less obscured in the developments that are daily altering the outlook of business. Industry to-day is very much regulated by the attitude of labor and their demands, and while these, to some extent, are in keeping with the general conditions, the disorganization that is resultant of strikes and wage demands, is not conducive to normal industrial enterprise. The mills are not disposed to accept far future bookings, owing to the uncertainty of production costs, and consumers are only covering their immediate needs, the principal reason being the same as that of the producers. Many of the steel districts in the States are either affected by labor troubles or by the threatened demand for increased wages, factors that may ultimately result in early shut-downs, or curtailment of output. The general effect of a strike of any magnitude is felt all along the line, and when production stops at one point, the falling off in demand is at once transmitted to all other branches. It is this unrest among employees that prevent a more liberal policy of reconstruction. Many manufacturers of steel supplies and products are disposed to operate on a low profit basis in an effort to curb the demands of the men, but if wage increases are granted it must mean a further advance in steel prices. Steel activity in this district is confined to current requirements of consumers and the demand is about normal. The curtailment of operations at the Sydney plant of the Dominion Iron and Steel Co. is affecting the other areas that supply the basic materials of the steel mill of the company. The production of ore at Wabana will gradually ease up as a result of the reduced requirements. The limestone quarries of the company in Newfoundland has also suspended operations, as about a year's supply is now on hand. With mill quotations firm, dealers here have made no change in prices.

Single Machines Predominate

No new developments have taken place in machine tools of late and the general situation is virtually the same as it has been for the past couple of months. The volume of business passing is not great, but is of a character to encourage the dealer. The number of sales is the feature of interest, and while few of these run not more than one or two machines, the greater distribution compensates for the loss of larger orders. Like many other industries, the machine tool business is affected by the labor unrest, directly in some cases and indirectly in others. Uncertainty is the keynote and expansion or extension of manufacturing is difficult under such conditions. Supplies are moving with the usual freedom, but purchases are almost exclusively confined to current requirements.

Scrap Again Quiet

Market speculation is the chief factor affecting old materials at the present time, as the quiet demand does not tend to move the price of scrap one way or another. Some increased buying was felt a few weeks back, but this has been replaced by another dull period, in which the metal moves but slowly. The season

of the year may be partly accountable for this condition, as steel business is generally more or less affected about this time of the year. The apex of a few weeks ago has again been taken off and quotations show the market at a lower level, but the tone is one where anything may happen and it would not be surprising to see another reaction next week, with prices stronger. Coppers have declined about 2 cents per lb. in the past two weeks. Brass scrap is more firm, but has declined slightly in red brass turnings, also light and medium brass, which are one cent easier. Several steel lines show declines. Rails are down to $14.50 per ton, a drop of $5.50 in about three weeks. Wrought iron pipe has declined from $11 to $8 per ton.

STEADY VOLUME OF BUYING

TORONTO.—While there is no big buying being done, there is a steady volume of small orders which make business in most lines very satisfactory. As one dealer remarked: "We expected after the armistice to be able to take a six months' rest, but haven't seen the change yet." The unsettled conditions in the labor market are no doubt responsible for some holding back on the part of buyers, there is enough being done to make a very respectable turnover. This applies to machine tools and machine shop supplies generally. There are no price changes to record in the steel market, but they are in the air. Chain manufacturers held a meeting last week at which the price of chain was discussed, and, though nothing has been announced, it is expected prices will go up shortly on this material. There is a good buying of warehouse stocks, the railways being responsible for some of it, but the automobile trade for the larger part. Mills making automobile sheets are far behind on orders, and will not promise delivery in less than four to six months. This turns the attention of the makers to other sources of supply, that is the warehouses. There is not much demand for structural steel.

POINTS IN WEEK'S MARKETING NOTES

The continued unrest in the labor market is discouraging buyers of steel. Building construction falling off.

* * *

Machine tool and machine shop supply dealers are doing good business, though there is no large single buying.

* * *

There has been a dull week in the scrap metal market, with a drop of prices in steel making grades.

* * *

The automobile trade is buying considerable quantities of sheets, and automobile and railway buying is keeping steel warehousemen busy.

* * *

Basic pig iron from the Lorraine district of France has been sold in England at a much lower price than the American iron.

CONCERN IS FELT FOR FUTURE OF STEEL BUSINESS

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., Aug. 21—A much more conservative spirit is shown by both buyers and sellers, owing to recent unsettling developments, chiefly in connection with labor. The increased labor unrest makes it questionable whether manufacturing operations can be maintained at all points. The steel producers are less concerned over their own labor outlook than over the outlook of their customers. There is a possibility of a strike in the steel industry, but the prospect is very far from a probability. At the Detroit convention, over a year ago, the American Federation of Labor decided upon an aggressive policy of attempting to unionize the steel industry. At the Atlantic City convention last June the reports admitted that little success had attended the efforts, but since then the federation has been striving more earnestly. The information gathered by steel producers indicates that up to date nothing by way of organization has been accomplished that would make it feasible to attempt a strike. While the steel makers are very painstaking in gathering information, they admit that the possibilities of there being a strike may be greater than their information indicates.

Much more concern, however, is felt regarding the future operations of the steel industry's customers. There are involved three general classes of steel consumers, the railroads, the ordinary manufacturing consumers and those who might engage in large construction jobs of an investment character, such as factories, hotel and office buildings, power plants, bridges and the like.

As to the railroads, the demands of the brotherhoods for the Plumb plan of tripartite control obviously serve to make the future of the railroads still more uncertain, that such a radical and unpopular plan would really be adopted is improbable, but the time when the railroads will be placed in a settled position and thereby be able to engage in work of rehabilitation and expansion is placed farther in the future. In normally good times the railroads take, in one form or another, from 15 to 25 per cent. of the steel industry's output, and after a period of several years of particularly stringent economy they might be expected to take more, but now they are taking practically no steel and they will take no tonnage of consequence until their position is assured. The attitude of labor disclosed in the past fortnight defers the time when the steel industry can expect the railroads to be large customers.

As to ordinary manufacturing consumers, there are some strikes, and possibilities of others, and each strike temporarily deprives the steel industry of a customer.

It has become a generally accepted view that when there is a full normal demand for steel at least half the tonnage passes into works of permanent construction, classifiable as investments. Such construction requires favorable prospects for its inception. The investor must be assured that he would not save much money, in first cost, by waiting a year or two, and he certainly must be assured that if the job were undertaken, labor and materials would be continuously available until completion, for until completion the money spent is earning nothing. The increased labor unrest now manifest is observed to be having a discouraging influence upon investors. An evidence of this is the rate at which contracts for fabricated steel work are being placed. This business was growing very nicely in the second quarter of the year, promising eventual establishment of a rate of buying equal to the capacity of the fabricating shops, but in the past week or two the contracting has been distinctly lighter than formerly.

Presumably, as a result of these developments there is now a much more conservative spirit throughout the iron and steel trade. Producers are less willing to enter into contracts, fearing they may have trouble in making deliveries, while buyers are still less willing to make contracts. The volume of strictly new buying is much lighter than a month ago, but the volume of shipping orders, made up chiefly of specifications on old contracts, is heavy and is easily in excess of the rate at which material is being shipped.

Merely from the viewpoint of the business that the steel industry does not get the situation and prospects appear far from favorable, but from another angle this makes the situation all the more favorable, because with all these defects in the market situation there is a large demand for steel. The mills are operating at about 80 per cent. of capacity and no one seems to doubt but that the material made and shipped is going directly into consumption. With many buyers, particularly the railroads and investors, not represented, or, but poorly represented in the market, the volume of tonnage taken by others is large, much larger than anyone would

have expected. With only a moderate volume of additional business the steel industry would be operating at capacity.

It is now fairly well established that there will be no advances in the important finished steel products this year, unless there should be a wage advance, which at the present time seems improbable. The only reason it seems worth while to mention the fact that price advances are altogether unlikely is that a few weeks ago many steel producers, for reasons that were not entirely obvious, were talking about the probability of there being price advances.

The local pig iron market is strong, at least on the surface, the furnaces that are in operation being well sold up, while there is a fair running demand. Occasional lots of surplus iron, however, are sold with such difficulty that it is evident there are no large unsatisfied requirements. There are many idle furnaces and it is only occasionally that a furnace blows in. A demand for pig iron that would give the furnaces even moderately full employment can hardly occur without the large steel works buying pig iron. This they do when they are pressed for tonnage and have to supplement their own pig iron make by outside purchases.

The scrap market became weak and inactive a fortnight or so ago and has not since improved. The mills are all out of the market as to heavy melting steel, though some of them intimate they may make some purchases in a few weeks. Heavy melting steel is off about $2 from its high point of three weeks ago.

SENTIMENT AGAINST PRICE ADVANCES

Special to CANADIAN MACHINERY.

EW YORK.—Though on a supply and demand basis, prices are due for a revision upwards, the sentiment is against any advance at the present time. This is on account both of the attitude of labor and the general result on the high cost of living. Makers are not taking orders far ahead, except where the purchaser is an old customer. There is no demand as yet for heavy shapes, the general investment demand not yet having come out. The Railroad Administration has an enquiry out for 100,000 tons of rails, but this is evoking but little interest. At the time of the last enquiry $55 was quoted.

Warehouse business is quiet, except in sheets, for which some sizable orders have been placed. In view of the probable car shortage mills are requesting that they be allowed to ship sheets in any cars available, protecting the stock as well as they can, but forwarding at buyer's risk. This impending shortage of cars and the probable advance of mill prices is expected to stiffen prices shortly.

There has been good business in cast iron pipe lately, but an enquiry for about 900 tons of six-inch and larger brought out some low prices. Prices last week quoted for 6-inch and heavier were $51 to $52.30.

HIGHER PRICES ALL ROUND

Special to CANADIAN MACHINERY.

From every point comes news of stiffening prices for pig iron. Probably the only point where this is not true is in the southern areas. Following are reports from the principal United States points:

New York.—There is considerable strength to the market here, and a brisk business, both domestic and foreign, is being done. Several thousand tons have been sold for United Kingdom, and enquiries amounting to nearly 200,000 tons for export are out. Central Foundry Co. purchased 10,000 tons foundry for delivery in last half and first half of 1920.

Boston.—Prices have made a general advance above the $28 Buffalo basis for No. 2X eastern iron. The advance is from $1 to $1.50 per ton. There has been some buying for first half delivery, and enquiry for last quarter and first half is good. New England sales during the week are around 7,500 tons.

Pittsburgh.—With makers of foundry iron well booked up for the remainder of the year, there is a tendency to look askance at 1920 business. This is due to the uncertainty of the labor market. The foundry men are feeling uneasy over the prospect of very much higher prices, $35 per ton having been mentioned as a possibility. Sales of foundry iron are around 20,000 tons.

Chicago.—There is not much enquiry, but a fair amount of selling is being done. Enquiries are being followed by sales with little delay. The strike of railroad shopmen has interfered with shipments, but not sufficiently to reduce the melt. The American Radiator Co. has purchased 4,000 tons for its Birmingham plant.

Buffalo.—There is a large volume of buying being done in spite of increase in prices. The aggregate sales amount to between 40,000 and 50,000 tons. Quotations are as follows: Basic, $26.75; No. 2 plain, $26 75 to $28; No. 2 X, $28 to $29; malleable, $27.25 to $29. Nearly all sales were for last half, a small proportion being for first half of 1920.

Cincinnati.—The situation here may be classified as a waiting one. There is not much prompt iron to be had, except in the case of furnaces which have off iron they are anxious to be rid of. The Jackson County district is tied up with labor troubles. While prices have been advanced no business is being done at the new rates.

St. Louis.—There has been a little buying for last quarter and first quarter of next year. 1.25 to 2.25 silicon is quoted at $26.75, with differentials on higher grades. Some foundries which had bought enough iron for their estimated consumption have had to purchase small additional tonnage.

Birmingham.—Selling is good, and it is expected that three more furnaces will be put in blast this month. There is no tendency to look for 1920 business on the part of furnaces, who are not even making any efforts for fourth quarter selling. No. 2 foundry is on a basis of $27.75.

Philadelphia. — While business has reached a fair aggregate total, it is much less than previous weeks. Furnaces are mostly asking higher prices. Copper free low phosphorus iron is quoted $36 to $38 furnace according to analysis.

LABOR UNREST UNSETTLES MARKET

Special to CANADIAN MACHINERY.

The market through various causes is unsettled. The labor situation is affecting the market in some cases, and prices have weakened. Following are quotations from various United States centres:

Boston.—Brisk business and tightening prices are in evidence here. There has been some buying of heavy melting steel for Pittsburgh delivery and prices ranged from $21 to $22.50. No. 1 machinery has been active and has sold at $28 for future delivery.

Philadelphia.—Steel scrap has weakened in some cases as much as $1 per ton from last week's prices. Cupola scrap on the other hand has shown greater strength, now being quoted at $25 to $26. The labor situation has been the cause of weakening in steel.

New York.—There is a good demand for steel making grades, although the Pittsburgh buyers are not in evidence. Pennsylvania buying is good for the eastern part of the state, and the quotations on heavy melting are from $15.35 to $16.50 f.o.b. New York. The labor situation is making buyers more cautious.

Pittsburgh.—With buyers inclined to stay out of the market till the labor situation is clearer, and other buyers being about stocked up, scrap has weakened in all grades. The drop is about $1 per ton all round.

Buffalo.—The scrap market is dull here, though it is probably but a temporary condition. Prices are being maintained, and it is thought that there will be renewed buying of heavy melting in the near future.

Cleveland.—Notwithstanding a weakened market, dealers are very hopeful for the future. They point out that the demand for the finished product is heavy, and this is bound to be reflected in the scrap market. A sale of heavy melting involving 50,000 tons is reported, the price ranging from $19 to $23.

Chicago.—Although prices have halted after the long-continued advance from the spring, it would only take a small resumption of buying to bring them back again. Here, as elsewhere, the uncertain state of the industrial world is affecting the scrap market, which is always susceptible to these influences. Quotations for spot business are some-

what lower than the lately prevailing rates.

Cincinnati.—A dull market with prices unchanged is the condition here. Dealers are slow in buying outside iron that may be held up in delivery, cars being scarce and the labor situation unsettled. Railroads are not offering anything.

Birmingham.—Buying is light, but prices remain firm. Heavy melting is quoted much higher than buyers are willing to consider. All grades show strength.

READERS—ATTENTION!

AS no doubt readers of CANADIAN MACHINERY are well aware, Toronto Exhibition opens on August 23rd. Mechanics as a rule make their headquarters the Machinery Hall while at this fair, so a word to the wise is sufficient.

At the east end of this Machinery Hall, the **Garlock & Walker Machinery Co.** are going to have a display of more than ordinary interest. They have taken over a very large space, in fact 1,400 square feet of floor area, in order to show to best advantage the various machine tools they intend exhibiting.

Many of these machines will be in actual operation, with experts from the various factories operating them at full capacity. These gentlemen have been brought for a two-fold purpose, first to demonstrate the field and scope of their machines, and second to answer any questions relative to these machines. They invite close inspection, and will be only too pleased to give those interested all possible information. They particularly desire that questions be asked.

Included in this exhibit will be:

A **"Gooley-Edlund Inc. Co. Briggs Miller."** Of course, the Briggs Miller is well known as a manufacturing miller with wonderful capacity, so that this feature will be of keen interest to those wishing greater production where a miller can be used to advantage.

Then there will be a **Steptoe 24 in. single pulley drive shaper,** also a **Bath No. 2 Universal Grinder,** adaptable to practically any grinding operation.

There will also be a **Fitchburg 8x36 Cylindrical Grinder,** whose qualifications are already well known to the machine trade.

A **heavy duty Ryerson-Conradson single pulley drive plain milling machine** will also be shown.

Another feature worth while will be a complete line of **Thor Pneumatic and Electric tools.** This alone is worthy of attention.

Some other interesting features will be a **Lodge & Shipley three step cone 24 in. engine lathe, a Sibley sliding head drill press, a Rockwood back geared drill, and an Edlund sensitive drill press.** All these will be of the latest design.

A **Kelley Routing Machine** will also be shown, with samples of work turned out by this interesting type of machine tool.

Perhaps two of the biggest features of this exhibit are the remaining ones to follow:

The first of these is the **Adams Short Cut Lathe.** This lathe has never been exhibited here before and will prove an eye-opener to the progressive manufacturer, foreman or mechanic. Compact, accurate and built for manufacturing duplicate parts, this machine is indeed a study in good design. Six changes of speed are provided in an all geared head, and automatic stops, etc., etc., form a part of its equipment.

Automobile manufacturers, or, in fact, anyone desirous of making duplicate parts, would do well to look into this new machine tool.

Last but not least comes a varied line of **Cataract Machinery.**

A **Cataract sensitive drill,** with countershaft and back drill chuck will be shown. **A No. 3 Cataract Lathe,** with automatic chuck closer, together with screw slotting device, and medium weight turret, will be exhibited. This machine will also have a double cross slide.

Then there will be a **No. 4 Cataract Lathe** with thread chasing attachment. There will also be a No. 3 lathe with screw cutting, grinding, face and angle plate attachments, fully equipped with drill chuck and scroll and independent chucks.

A **No. 4 Cataract Bench Miller** will also be shown.

A **No. 7 Cataract Turret Tool Post lathe** will also form a part of this exhibit.

To show that a series of machines may be self-contained, the **Cataract** exhibit will also include an **R4 underdrive bench outfit.**

This arrangement will show four lathes, all self-contained and mounted on a special stand, together with a special underdrive.

A motor in convenient position on framework will drive the complete outfit.

Other interesting machines will also be shown, but space does not permit of further detail.

Enough to say to our readers in general that a visit to this exhibit will more than repay them for time spent in looking over this up-to-the-minute company's effort to place before those interested, a complete and varied line of machine tool equipment.

The McAlear Manufacturing Co. has recently moved into a new factory at Southwestern Avenue, Chicago, where they will manufacture their complete line of power plant and heating specialties, including packless radiator valves. They are issuing a new catalogue, dealing with these lines, which will be forwarded on request to any interested party.

The Algoma Steel Co. will have completed by November 1st their new rolling mills, wherein they will be able to manufacture beams and channels up to and including 15 in.; Z bars, rounds and squares, up to 14 in., and angles from 6 by 6 in. to 1¼ by 1¼ in.

Diamonds to the value of $856,000,000 have been mined in South Africa.

RECEIVE IMPERIAL SERVICE MEDAL

The following servants of the Canadian Department of Railways and Canals have been awarded the Imperial Service Medal:

Albert J. Atkinson, time-keeper, Moncton; Placide Babineau, carpenter, Moncton; Alexander Bain, station agent, Riverdale; Geo. T. Biddington, locomotive fireman, Moncton; John S. Cameron, section foreman, Penniac; W. D. Cantwell, toolroom keeper, Charlottetown; John Corbett, section foreman, Moncton; Harry Cummings, hostler, Stellarton; Aime Dumas, conductor, Riviere du Loup; John A. Fraser, machinist, Moncton; J. M. Grant, section foreman, Riviere du Loup; Jos. Guay, brakeman, Levis; Alfred Lebel, conductor, Riviere du Loup; Charles Mercier, engineman, Riviere du Loup; R. W. Orchard, conductor, Mont Joli; Jules P. Parent, engineman, Riviere du Loup; A. C. Reid, carpenter, Moncton; Francis W. Rioux, engineman, Riviere du Loup; Jos. Scott, engineman, Riviere du Loup; Benjamin Steeves, section foreman, Campbellton; Matthew C. Webster, station agent, Pictou; Job Yeo, engineman, Charlottetown.

"What a different world this would be if we used our eyes to see the best in others and encouraged each other by speaking of it."—The Three Partners.

Don't let your competitors fix the price of your product—fix it yourself to cover your costs and a reasonable profit.

Apply common-sense with your cost system. The easiest way sometimes is the best way. Keep everything simple. Don't make anything harder than it ought to be. But remember to keep the main idea constantly in view—"I want to know my costs!"

Ho! ye who in the workshop toil and sweat the long day through, remember that it's harder still to have no work to do. Ho! all who labor, all who strive, ye wield a mighty power. Do with your will, do with your might, fill every golden hour. The glorious privilege to **DO** is man's most noble dower.

A concern has been formed in Denmark to begin the manufacture of typewriters.

It is said that the waste of timber in the yellow pine industry alone is sufficient to furnish raw material for the daily production of 40,000 tons of paper, 3,000 tons of rosin, 300,000 gallons of turpentine and 600,000 gallons of grain alcohol.

An American contemporary prefers the old name of "hobo" because it is easier to pronounce than the modern name of "Bolshevik."

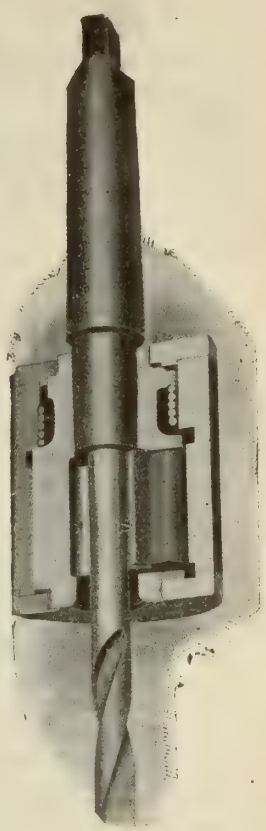
Use Wahlstrom Chucks

POSITIVE DRIVE
AUTOMATICALLY
SELF-CENTERING
NO SLIPPAGE

Aikenhead's

Wahlstrom Attachment



Speed Up Production in Your Machine Shop

Consider the merits of an automatic chuck that keeps the spindle of every drill press running without a second's stop.

Calculate the money value of the minutes saved by the Wahlstrom chuck each time a tool is changed.

The Wahlstrom chuck—not the operator—centres the tool perfectly. It enables the operator to make tool changes in less than two seconds. Spindle of machine never stops. And there is absolutely no delay because of tool slippage. For no tool gripped by the jaws of a Wahlstrom chuck can slip. If the resistance on the tool is great, the holding power of the jaws increases.

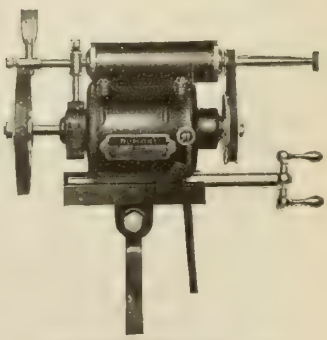
DUMORE ELECTRIC GRINDERS



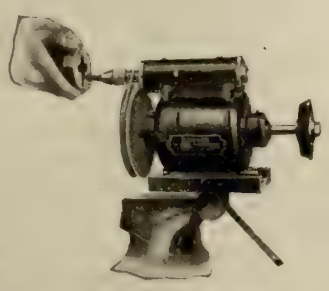
EQUIPMENT A

General Tool Room use. Includes high-speed internal spindle. Reach, 2 inches; speed 30,000 R.P.M.; motor spindle speed, 10,000 R.P.M.

Invaluable for Accurate Grinding of Tools

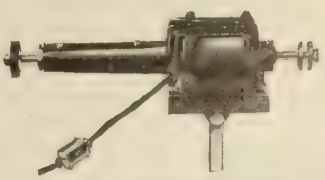
These grinders are designed to meet the requirements of the manufacturer who desires a light grinder which will do accurate work, and at the same time does not wish to invest in a large and more expensive tool. The Dumore grinder can be quickly attached to lathes or other machine shop equipment. Their scientific construction entirely eliminates vibration and work done is accurate and free from chatter marks.

Write to-day for descriptive literature.



EQUIPMENT C

Button Die Grinder. Speed 50,000 R.P.M.



EQUIPMENT B

Deep Internal Work. 10-inch extension arm. Speed, 10,000 R.P.M.

AIKENHEAD HARDWARE, LIMITED

17 TEMPERANCE STREET, TORONTO

RESEARCH IN METALLURGY

Scientific research in metals and their properties has made considerable progress during the last few years, and the results of the work done is startlingly shown in the proceedings at the annual meeting of the Institute of Metals, held in London.

A paper by Dr. Rosenhain describes the method of preparation of a number of copper alloys and gives the results of tensile and hardness tests carried out on them. The alloys were intended to meet very stringent requirements involving extensive cold-working, so that high tensile strength with great ductility was aimed at. The alloys dealt with fall into two main classes. The first class consists of alloys of copper with aluminum, with manganese, and with both aluminum and manganese. Difficulties were experienced in casting these alloys into slabs, and special methods of casting were adopted. A process sometimes known as "pressure casting" which has been developed and patented by Mr. F. Tomlinson, was eventually adapted for use with these alloys and proved very successful. In this method the liquid metal is forced, by means of externally applied air pressure, through a feeder tube dipping into the molten metal nearly to the bottom of the crucible and communicating with the bottom of the mold. Alloys cast by this method were subsequently rolled into strips. The results of tensile tests show that a very high degree of ductility can be obtained, together with considerable tensile strength, by the use of manganese. For example, the alloy containing 7 per cent. aluminum without manganese has a tensile strength of just under 40 tons per square inch, with an elongation of 17.5 per cent. in the "as rolled" condition, while after annealing it still has a tensile strength of 27.5 tons per square inch, and the remarkable elongation of 71 per cent. The second class consists of alloys containing no aluminum; these are mainly combinations of manganese and zinc, or nickel and zinc, with copper. They were cast successfully with the aid of borax as a flux, and were subsequently rolled into thin strips of excellent quality. Of this series the strongest alloy is that containing 3 per cent. manganese and 10 per cent. zinc, which, in the old rolled condition has a tensile strength of 47 tons per square inch, with an elongation of 3 per cent., and in the annealed condition a tensile strength of 23 tons per square inch, with 36 per cent. elongation.

The effect of work on the metals and their alloys has elicited considerable attention of late years and the variations in their physical and mechanical condition that result from the application of work have been very fully investigated. Hitherto the hard metals and alloys have received the closest attention, whilst such metals as tin and lead have scarcely been considered. This is unfortunate, since many of the phenomena with which one is confronted in the case of the cold-worked hard metals and alloys might, by much study, be rendered explicable.

The researches of Goerens and Webster (among others) and of Alkins, in particular, have demonstrated that a very marked change in the physical and mechanical condition of the metals and their alloys is reached when the same have been deformed by certain well-defined amounts. Alkins, for example, has shown that when a copper bolt, previously annealed at 600 deg. C., and 9-16 in. in diameter, has been reduced in diameter about 29 per cent., it is so changed in condition that its ultimate strength in tension tends towards a constant value over a narrow range of reduction.

It has now been determined by Mr. Owen W. Ellis that the effect of cold-work upon a 39 per cent. zinc-copper alloy that he finds evidences of an inversion in the mechanical properties of the alloy in the neighborhood of 58 per cent. reduction in thickness of a strip. While the results of tensile tests of samples of the material that have been subjected to varying degrees of deformation are not of themselves conclusive, the results of Brinell hardness tests and of micrographic examination appear to afford satisfying evidence of a somewhat similar phenomenon to that recorded by Alkins.

An explanation of this peculiar change in condition is thought to be found in an extension of the law of annealing for strained metals and solid solutions propounded by Hanson at the last meeting of the Institute of Metals. This law stated that "for every degree of deformation there is a critical recrystallization temperature at which crystal growth is extremely rapid, and the size of the crystals produced by this rapid growth is the greater the smaller amount of deformation proceeding such annealing." This law appears to admit of the possibility of the temperature of the working of the metal or alloy coinciding with the "critical recrystallization temperature at which crystal growth is extremely rapid." It might even be inferred that the converse of the above law is true.

The process of cold work, viewed in the light of Reilby's theory, may be considered to result in the production of amorphous matter at the expense of the crystalline matter. It is suggested that there is at all stages of deformation a tendency for the reaction to take place, and that as the deformation to which the material has been subjected increases, so does this reaction continue, suffering a change in its rate when the critical degree or range of deformation has been attained. A graphic representation of these conditions results in the drafting of a curve representing the relation between the degree of deformation and the mechanical property which is almost identical in type to those obtained as a result of mechanical test.

A remarkable proof of the existence of the inversion in other alloys of copper is also afforded by the results of experiments made with a view to determine the power absorbed in the rolling of alloy strip. The power-reduction curves for 70-30 brass and for 20 per cent. nickel-copper for example, show most sharply-defined changes in direction, these changes in direction appearing to vary according as the mass of the material to be treated is changed.

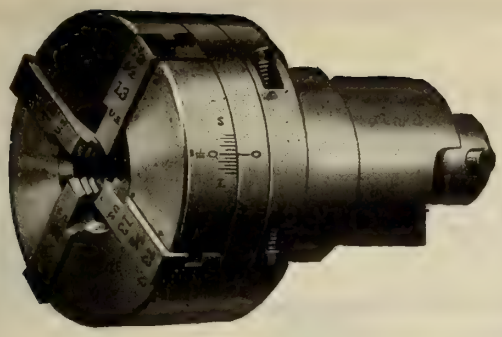
The above hypothesis as to the nature of the inversion in the property-deformation curves of the metals and alloys has been put forward, but no definite reason as to the cause of the inversion has been given. The processes of rolling and of drawing are such as result in the formation of a "strain gradient," to employ a term introduced by Jeffries, of most pronounced character within the materials undergoing deformation. As Jeffries has shown, a strain gradient produces a recrystallization gradient, and this, under proper temperature conditions, will produce exaggerated grain growth according to the germinative hypothesis. That the proper temperature conditions may be obtained, provided deformation is carried to sufficient extent, has, it is thought, been proved.

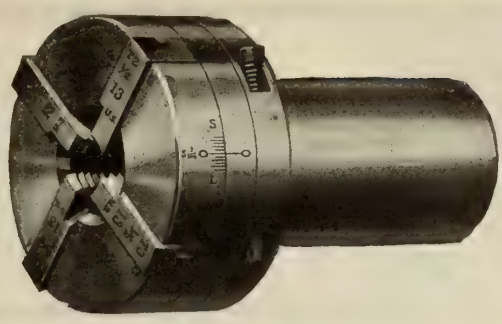
That these things are of intensely practical value must be patent to all and not to those concerned with the cold-working of metal alone. Both users and manufacturers of extruded rod, for example, have seen, not a few times, material showing very obvious signs of exaggerated grain growth. That this result may be obtained in the actual process of extrusion, given the correct conditions of temperature and of deformation, appears to probable rather than possible.

In conclusion, Mr. Ellis refers also to the exaggerated grain growth that may be produced as a result of stamping certain zinc—coper alloys—not, happily of the best types for general engineering work, within certain temperature ranges.

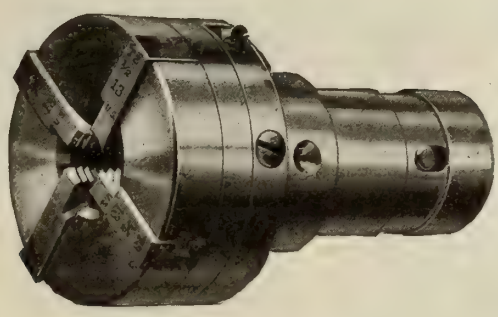
The tenacity-reduction curve shows a marked check in the rate of increase of tenacity at about 50 per cent. reduction in thickness, corresponding to the change of state, previously shown by Alkins to result from the progressive cold drawing of copper wire at a similar stage of reduction. There is a corresponding change in rate of decrease of percentage elongation and in rate of increase of scleroscopic hardness. The existence of another change at 80 per cent. reduction is suspected, as indicated by inflections in the tenacity curve, and the hardness curves. The scleroscope-hardness figures reach a maximum at this stage, but the auto-punch figures show a marked acceleration in the rate of increase.

A limited number of annealing experiments were carried out at temperatures of 600, 750 and 800 degrees centigrade, and the results point to incompleteness of softening of the severely worked strips as compared with the moderately-worked strips. The results of tensile tests, hardness test, and microscopic examination are in agreement, whilst scleroscopic tests on strips annealed at 750 deg. V., indicate the existence of a maximum at about 80 per cent. reduction. With the more severely worked specimens, after annealing, the strain structure on the polished and etched surfaces is visible without the aid of a microscope.





Geometric Solid Adjustable Die Heads



When one uses the word "ONLY," he needs to be sure of what he is talking about. With confidence we use the word in saying that a Geometric Solid Adjustable Die Head, fitted with a set of milled dies, is the only solid die head that will back off without stripping the thread.

Geometric Solid Adjustable Die Heads may be fitted with either a releasing shank, plain shank, or with special shank for the Gridley Automatics. The releasing shank permits the head to disengage from the shank upon completion of the thread. The plain shank fits the head for use on the turret of a lathe or on a live spindle, such as a drill press.

Apart from the fact that it is not equipped with the self-opening feature or the roughing and finishing attachment, the Geometric Solid Adjustable Die Head is the same in principle and construction and will do equally as accurate work as the other styles of Geometric Die Heads.

Whatever the requirements, there is a type of Geometric Die Head best adapted to the work.

TRADE GOSSIP

Bond House Expands.—The Atlas Bond and Security Corporation, which recently underwrote the securities of the Anglin Norcross Construction Company, has opened branches in Toronto and Ottawa.

To Manufacture Fish Leather.—An American firm has been looking over the ground in Kingston, Jamaica, with a view to establishing a tannery for fish hides. The skins used would be those of sharks and other non-scaly fish.

Strike Thought Broken.—The Mine Managers' Association has held a meeting with the executive committee of the proposed new union of miners. They did not give out any statement of what transpired, but it is generally thought that the back of the strike has been broken.

Railway Shop Busy. — The Leaside shops of the Canadian National Railway are pretty busy these days. There are about twenty locomotives in the shops for repairs besides several coaches. About 300 men are employed at present, and skilled mechanics are being taken on daily.

Good Crop Prospect.—The Ontario crop situation is very promising, according to the Ontario Commissioner of Agriculture. Crops in Northern Ontario are further ahead this year than they have been at the corresponding time in previous years.

New Re-insurance Corporation. — A new company known as the Re-Insurance Corporation, Ltd., has been incorporated in England with a capital of £500,000, the shares being of the par value of £1. The corporation is closely associated with the Yorkshire Insurance Company.

New Toronto Factory.—A new suspender plant is to be erected on Spadina Avenue between Adelaide and Richmond Street at an estimated cost of $135,000. Mr. Henry Greisman, head of the King Suspender Company, is the interested party. The building will be of mill construction and be six storeys high.

New Cable Line.—As a result of the long-felt dissatisfaction with the Pacific cable service between the U. S. and Japan, a group of Japanese business men are floating a company with a capital of about $25 000 000 for laying a new cable line. American capital will likely be enlisted as well as Japanese.

Guelph Industry Expands.—The International Malleable Iron Company of Guelph have called for tenders for the construction of a new machine shop and warehouse. The building will be one storey in height and will be 189 feet by 120 feet, of concrete and brick, and will cost about $33,000. The architect is W. A. Maloney.

Motion to Wind Up.—A number of the shareholders of the Imperial Steel & Wire Company having made an application for the winding up of the company, Mr. Justice Kelly has adjourned the application to September 11th. In the meantime he has appointed Mr. G. T. Clarkson to make an examination into the affairs of the company.

Good Roads Movement.—It is understood that the Government is about to appoint an honorary advisory board which would assist the Department of Railways and Canals in its work for good roads. The personnel of the new board is stated to be made up of the following gentlemen: Mr. C. A. Magrath, late fuel commissioner; J. P. Mullarkey, of Montreal, and Mr. Home Smith.

Kingston Wants Elevators.—Kingston is going to make a bid to be the grain transhipment port in place of Port Colborne. The city council is going to urge the Dominion Government to build large elevators there. They point out that it will take two years to rebuild the elevator at Port Colborne and by that time the Welland Canal will be finished and Kingston will be the logical point for the steamers to bring their grain cargoes.

Pulp Mill Changes Hands.—The Aroostook Pulp and Paper Mill, which has been closed for some weeks, will be taken over and operated by a new company. The plant was built in 1917 and is well equipped, having a daily capacity of 60 tons, and employing about 200 men. The interest has been purchased by Mr. Gould and H. B. Stebney of Boston, and the plant will soon be in full operation and eventually will be extended. Mr. A. R. Gould, the president of the new company, is well known through his connection with the St. John Valley Railway.

New Welland Measurements. — The Department of Railways and Canals has issued a report on the alterations to the Welland Ship Canal. Its present length is 26¾ miles and comprises 25 lift locks, the dimensions of which are 270 feet by 45 feet, with a depth of water on the sills of 14 feet. The proposed canal will be 25 miles long, and the number of locks will be reduced to seven. These locks will be 800 feet in length by 80 feet in width in the clear, and the depth of water on the sills at extreme low water in the lakes will be 30 feet. The width of the canal at bottom will be 200 feet, and for the present the canal reaches will only be excavated to a depth of 25 feet.

Salving Port Colborne Grain.—It is understood that practically all the grain which was stored in the destroyed elevator at Port Colborne, owned by the United States Government, will be saved. It will be shipped to Montreal for transhipment overseas. In connection with this, a meeting was held in Montreal between the Harbor Commissioners, the Railway Board and the city Administrative Commission, when it was decided to put in two extra tracks on the harbor front to handle the extra grain. It was estimated that some 60,000,000 bushels would be shipped to Montreal from Port Colborne.

Airplane for Morrisburg.—Handley-Page, Ltd., have secured a Dominion charter to engage in a general aeroplane business in Canada. The capital stock will be $2,500,000, and the head offices of the company will be at Morrisburg, Ont. The directors named are William Harold and Admiral Mark Kerr, London, Eng.; Harry Clark, Montreal; Fred Chalmers and W. H. Gannon of Morrisburg.

Bridge Destroyed by Fire.—The forest fires that are sweeping Deer Lake have destroyed the C. N. R. bridge between Deer Lake and Burger. The C. N. R. trains are using the C. P. R. tracks for their through traffic. The local service is completely tied up. Alarm is felt for several families of settlers of whom no word has been heard for some days.

PERSONALS

Mr. M. W. Ferguson, who has been in the employ of the city of St. Thomas for the past six years as city engineer, has resigned his position.

Mr. D. A. R. McCannel has been appointed city engineer for the city of Regina. He has been in the service of the city since 1911, and for the past two years has been acting city engineer.

Mr. M. L. Cantell, C.E., has been elected a member of the Royal Society of London, England, according to recent advices. Mr. Cantell is a Provincial Government engineer of Manitoba, and resides at St. Boniface.

"Yes, Tom, you're right. The DUMORE grinder will mean better dies and gauges for us. I'll order one today."

TO every shop making its own gauges, jigs or dies the DUMORE grinder has real significance. If you are looking for less trouble and greater accuracy in your grinding of hardened tools you will find the means right here.

Chatter-marks, taper and bell-mouth are eliminated through the use of a DUMORE. And the two reasons for this lie in the high spindle speed and dynamic balance of the armature. Even small wheels are thus given the correct cutting speed without a possibility of vibration. The DUMORE grinder is light and portable—easily carried from one part of a shop to the other and quickly set up on a lathe, shaper or milling-machine.

If you would improve your tool grinding standards—if you would obtain absolutely accurate results in shortest time, you should install a DUMORE. Ask your jobber to show the tool, or write us today for illustrated literature.

WISCONSIN ELECTRIC CO.

2912 16th Street RACINE, WIS.

The Board of Education of Peterborough are asking for tenders for a public school. Tenders will be received up to September 1 and plans and specifications can be obtained from W. & W. R. L. Blackwell, architects, Room 17, Bank of Commerce Building, Peterborough, or Melvern F. Thomas, 229 College Street, Toronto.

The Toronto Board of Education are asking tenders for an addition to Keele Street School. Tenders open till August 27. Specifications and information can be obtained at the office of Messrs. Chapman & Oxley, Harbor Commission Building, Toronto. Tenders will also be received by the same authority for addition to the Duke of Connaught School, Morley Avenue, and specifications can be obtained from the architect, Mr. J. Siddall, 250 Confederation Life Building, Toronto.

MARINE

Washington.—The United States War Department has announced the assignment of four of the fastest transports to the mail service between New York and Brest. The four vessels will be the George Washington, Leviathan, Agamemnon and America. The Shipping Board has now received 3,000,000 tons of shipping from the army authorities.

Sydney, N.S.—The huge Bayley raft, which was being towed over to Europe by the ocean-going tug Humber, broke adrift in a heavy gale off the coast. The tug has arrived in Sydney with part of the raft, and will proceed to sea to pick up the other part immediately. The raft has been ready for sea for the last two years, but owing to war conditions could not be taken across.

Port Stanley.—A diver is to be sent down to examine the hulk of the vessel discovered between Port Stanley and Rondeau. This is thought to be the wreck of the car ferry Bessemer, for which an unsuccessful search has so long been kept up. Pieces of the wreck were pulled up as much as two hundred feet apart, and this inclines the captain of

Gorgeous spectacle—Festival of Triumph—1,500 performers.

the searching tug to the opinion that he has at last discovered the missing vessel.

New York.—Word was received by wireless here that a collision had taken place off the Jersey coast between the outbound United States Shipping Board steamer Point Judith and the Norwegian steamer John Blumer. The John Blumer returned to New York in tow. The Point Judith was built by the Shipping Board last year, and is a vessel of 1,699 tons. The John Blumer is owned by C. H. Sorensen, and was built in 1914 and registered 1,481 tons.

Vessel Tears Out Gates.—The steamer Aztec, of Buffalo, while entering Lock 17 of Cornwall Canal, snapped a rope, and the way on the vessel caused her to push open the lock gates. The result was to put the lock in communication with the high level water, which rushed in and tore the gates away completely. The resulting flooding of the surrounding country resulted in the drowning of a boy who was on the bank, and two companions had a narrow escape of sharing his fate. They saved themselves by climbing a telegraph pole.

OBITUARY

The death occurred recently at the residence of his father, 676 Shaw St., Toronto, of Edmund F. Bradley. Death was due to heart failure. Mr. Bradley was local manager of the Erie City Iron Works.

From Saranac Lake, N.Y., comes the announcement of the death of Mr. Wayland Williams, of Laurie & Lamb, engineers, Montreal. Mr. Williams, who was 52 years of age, was at one time connected with the famous old Laurie Engine Works.

Mr. Samuel G. Lester, who was master mechanic of the Dominion Bridge Company, Ltd., died suddenly at the Royal Victoria Hospital, Montreal. He was 43 years of age, and for twenty-one years had been in the employ of the Bridge Co. He is survived by a wife and one daughter. He was a son of the late William Lester, of Toronto.

One of the things we all do well is to forget.

Names that were household words yesterday are gone to-day.

Because people knew your Name and your Line a year ago it is no sign they do to-day. They forget easily.

Keep yourself in the public mind by advertising. It is just as important to make old friends remember as it is to win new friends. Advertising does both.

MILWAUKEE MILLING MACHINES

Double Overarm maintains alignment.

It is impossible for the operator to place the arbor supports on the arbor and double overarm in any other way than in line. Arbor cannot be pounded out of line when using large, coarse pitch cutters on rough, heavy work.

Other Distinctive Milwaukee Features:

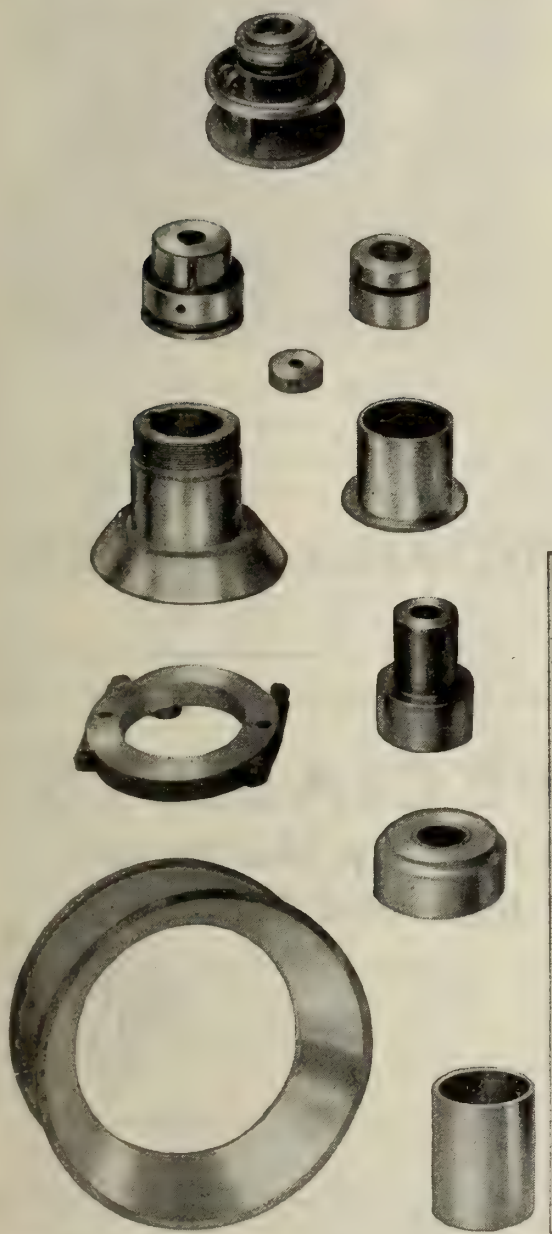
Solid top knee—hardened steel gearing and shafts in the column and feed box—automatic flooded lubrication — one and one-half gallons of oil per minute pouring over all gears and bearings in the column and feed box, insuring lubrication at all times—flanged spindle with hardened steel collar for driving arbors—constant speed drive, reverse being self-contained.

Send for our No. 21 Catalogue. Illustrating and describing Milwaukee Milling Machines and accessories in detail

KEARNEY & TRECKER CO.
MILWAUKEE, WIS. U.S.A.

FINISH

And Link-Belt Silent Chain Drives



THESE illustrations show some recently-completed parts machined on tools driven by Link-Belt Silent Chain Drives. In reproducing them in halftone it is impossible to show the smooth, even finish on each part just as it left the machine tool——But

Like all other parts completed on machine tools driven by Link-Belt Silent Chain Drives, these parts are smooth and clean cut, without chatter marks. Write for booklet No. 312 describing Link-Belt Silent Chain—the efficient drive for machine tools.

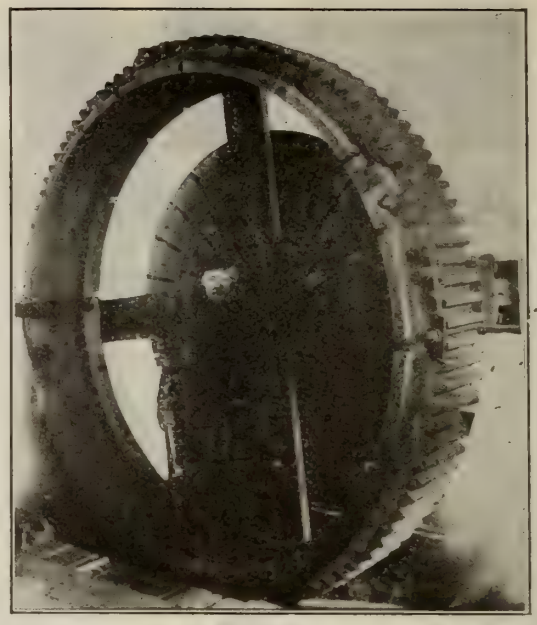
LINK-BELT
SILENT CHAIN DRIVES

Economy A Big Factor In "HISCO" Moulded Gears

In the installation of new machinery in the working out of new processes—you may require gears or sets of gears, and no matter what the diameter, the Hesco process relieves you of the necessity of having patterns made—entailing considerable cost and delay.



"HISCO" machine moulded gears, while requiring no pattern, insure accuracy, dependability, quality, and the price is minus the cost of patterns—which in these days of high lumber and wages, and when time is a factor—is something to be considered.

The "HISCO" plant is equipped to produce machine moulded gears up to 18 feet in diameter without patterns—and remember, very often the pattern has cost more than the gears.

International Machinery and Supply Company, Limited

371 St. James St., Montreal

The City of St. Catharines

TO the manufacturer seeking an ideal location for a factory site the City of St. Catharines offers indisputable advantages. Cheap power, convenient shipping facilities and plenty of high-grade labor are features of St. Catharines as a manufacturing centre. The city offers liberal inducements to machine, iron and metal working concerns which are worthy of investigation.

Facts about St. Catharines

CHEAP POWER—City owns Hydro-Electric Light and Power System; rates exceptionally low. 60,000 H.P. development of the Dominion Power & Transmission Co., Ltd., two miles south of the city with local distribution system.

TRANSPORTATION—Situated on C.N.R., G.T.R. and Welland Canal. Dominion Express and Canadian Express in operation. Steamer line to Toronto. Electric railway line to Niagara Falls, Welland, Port Colborne, Niagara-on-the-Lake, Port Dalhousie, Merritton and Thorold.

LABOR—Building of Workingmen's houses is an outstanding feature of St. Catharines. The city has a good class of contented labor and has as a rule been remarkably free from labor troubles.

SPECIAL INDUCEMENTS — The city is prepared to co-operate with new concerns and offers attractive inducements to all worth-while industrial projects.

GENERAL—Population, 19,500. City has up-to-date street railway, electric, gas, water, and sewage system. Centre of Niagara fruit belt. Industrially the district now includes principally metal industries and pulp and paper mills, several silk, woollen and hair cloth factories, auto tire and rubber footwear industries, and numerous industries connected with the fruit products of the district.

Write to the secretary of the Board of Trade for full information about the City of rare opportunities. Enquiries gladly answered.

War Record Not Made Public

The "Whitney" Special Quality "Type M" Chains

made a great showing during the war years 1916-7 and 1918.

Our tests and demonstrations were made on prominent 8-cylinder motors in service on a large number of cars in the State of Connecticut.

During this long period not a single "Whitney" Chain or Sprocket had to be replaced and the condition of every Drive has been pronounced remarkable.

One Drive recently examined had given over 35,000 miles' service and both Chains and Sprockets were in such perfect condition that they appeared good for more than double that record (Sprockets having no adjustment).

The links of this SPECIAL CHAIN have finished faces and reamed holes, and the smooth faces do not damage the Sprocket teeth.

Our war contracts were such that we did not announce this SPECIAL CHAIN until after the conflict was over.

Six Post Readers in New Cabinet

FORMER Finance Minister Cashen, who, following the crisis which led to the resignation of Premier Lloyd, of Newfoundland, has been called upon to form a Ministry, has already selected nine members to act with him.

Six of these, including the Premier himself, have been regular readers of THE FINANCIAL POST for some time.

This does not only indicate the quality as well as the extent of our circulation, but indicates also that men who carry big responsibilities find THE POST of value to them. It indicates, therefore, the approval which is meeting the effort of our editors and the great importance and value of the business information to which subscribers have access through the columns of THE FINANCIAL POST.

When the Government of Newfoundland was recently arranging the flotation of a $5,000,000 bond issue THE POST'S opinion as regards some methods of marketing was quoted by members of the Cabinet.

The Financial Post at Ottawa

IN the Dominion House of Commons the other week the attention of the Government was drawn to an article in THE FINANCIAL POST containing a reference to the financing of Roumanian orders through an agency established in London by Sir Clifford Sifton. Sir Thomas White mentioned that in reading his FINANCIAL POST that week, he had formed the opinion that the reference was to private marketing of bonds.

Keen Business Men and Cabinet Ministers Read the Post

SIR THOMAS WHITE, with other Cabinet Ministers and prominent Canadian men of affairs, have found THE FINANCIAL POST of swift and sure business service. When you "get down to business" you want the plain facts—all of them—without frills—and quickly. You get them like that in THE POST. THE FINANCIAL POST will keep you informed on Canadian business matters in a way unrivalled by any other publication. Send for a subscription to-day. The price is $3.00 per year, and you have only to fill in this form:

The MacLean Publishing Co.,
143-153 University Ave., Toronto.

Send me THE FINANCIAL POST every week till further ordered. I will pay subscription price, $3.00 per year, on receipt of bill, or you may draw on me for this.

The Secret of the Strikes

Most Canadians are asking "What is the cause of the 'Great Unrest' "? Is it the fault of labor—or of capital?—or is it the result of German propaganda? Do you know of the real reason for the labor disturbances in Canada, and elsewhere? Are YOU thoroughly familiar with the ins-and-outs of the plans which threaten a world-wide "tie-up?" This is something that should be understood by every Canadian. And every Canadian should read "The Secret of the Strikes," by Lieut.-Colonel J. B. Maclean in the August issue of MacLean's Magazine. It is brimful of startling and authoritative information regarding this great problem. Read it carefully. It starts on page 33, August MacLean's.

"The Lecturer At Large"

Stephen Leacock is one of the continent's greatest humorists. "The Lecturer at Large" is one of the best humorous sketches that he has written. It is made up of what he terms "a few painful reminiscences of the platform" in the course of his lecturing up and down Canada. Get your family around you and read the sketch aloud—it's a rare treat.

Other Big Features

"A Party in the Making." By J. K. Munro. Illustrated by William Casey. An article on the political situation, giving a great deal of inside information with reference to recent developments at Ottawa.

"Solving the Problem of the Arctic." By Vilhjalmur Stefansson. The fifth instalment of his story of the five years' explorations that he conducted for the Dominion of Canada.

"The Unspoiled Country." By Harold C. Lowrey. A descriptive article of a part of Canada which is little known to Canadians generally, Temagami.

"Petite Simunde." By Arthur Beverley Baxter. Illustrated by E. J. Dinsmore. A charming romance of the war. The author will be remembered favorably for his "Mr. Craighouse of New York, Satirist."

"The Seven Blue Doves." By W. A. Fraser. Illustrated by Charles L. Wrenn. The fifth of the Bulldog Carney series and in some respects the best. It is a mystery story.

"His Majesty's Well-Beloved." By Baroness Orczy. Illustrated by C. F. Peters. The second instalment of this splendid romantic novel of the colorful era of Charles II.

The Month's Vital Question

Turn to page 34, August MACLEAN'S, and you will find timely and interesting information regarding the High Cost of Living—a problem of large proportions.

The Review of Reviews

Here are a few of the articles chosen as the best published during the past month in all magazines:—Britain Winning Supremacy of the Air; Has Japan Two Governments?; Kaiser Employed Famous Beauties; The New Triple Alliance; Mammoth Animals in Alberta.

Try it Yourself

The best argument in favor of throwing away files the moment they become dull is to try filing a job yourself with a dull file.

If it makes you irritable, think what effect it must have on a man who has to file all day long.

Don't let your men work with dull files. Tell them to turn them in when they become dull.

When buying, specify Famous Five Files. You get a good run of sharp service from them because each file is accurately cut, well balanced and properly hardened.

NATCO

On Flange Work

The drilling of 15 Rear Axle Truck Housings is completed every hour. Each housing has 10 holes 1⅜ in. deep, which are drilled in one operation by the NATCO

The Maxwell Motor Company of Newcastle, Indiana, gives the information in this instance.

The machine is equipped with the NATCO patented feature—independent change of speed for each spindle—making it possible to drill, ream, tap, counterbore or spotface different size holes in one operation. Greater production, lowered costs and dependable accuracy are NATCO results whenever the work calls for operations on more than one hole.

NATCOs are built in 11 sizes ranging from 2 to 72 spindles.

We also design and build jigs and fixtures for use in connection with the NATCO Multi-Drillers.

The Canadian Disc Sander is 90% Dustless

Think what a godsend that it is to the pattern shop! Hundreds of prominent concerns are profiting immensely by using these sanders.

Two types of Canadian sanders are built—the Disc Sander and the Oscillating Spindle Sander. Both machines are equipped with New Departure ball bearings and General Electric motor. The table in each case can be tilted by a hand adjustment, 45 degrees down or 15 degrees up. Power is obtained by plugging into a lamp socket. Canadian Sanders are extraordinarily well built and are guaranteed against all defects.

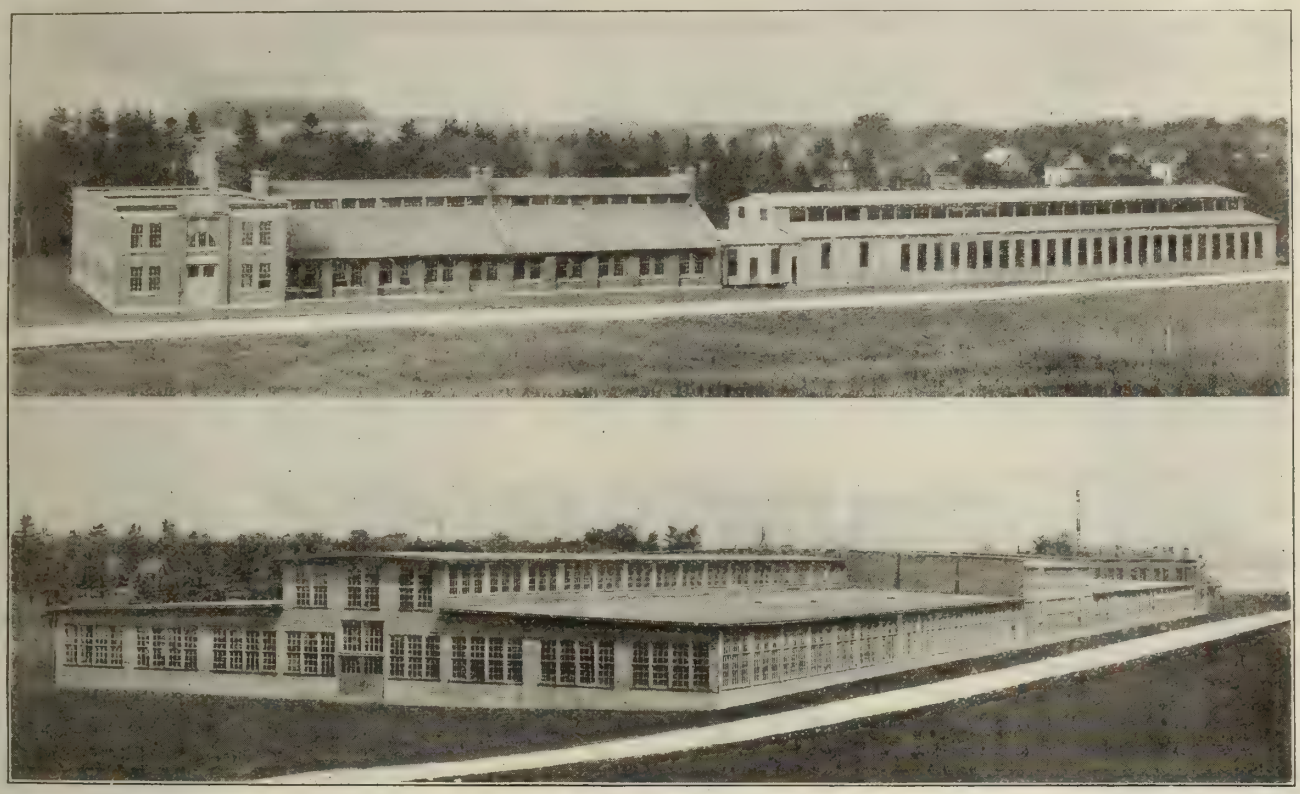
PLANT FOR SALE

A large plant, idle since shell-making stopped, for sale at a very low price.

Total floor space, 109,500 sq. ft.



PLANT OF PEMBROKE IRON WORKS LIMITED
PEMBROKE, ONT.

Total area of property, nine acres.

This large plant, consisting of three separate buildings, approximately 1,000 ft. long, with a width of from 50 to 140 ft., has a floor space of about 109,500 sq. ft., and with an area of nine acres gives ample room for storage or expansion. The large building at the bottom contains 85,000 sq. ft., built in 1918, frame construction ; building in upper left, built in 1909 for a stove foundry, brick construction, has a cupola, contains 18,380 sq. ft.; building in upper right, frame construction, built in 1916, contains 5,520 sq. ft. These three buildings can be used separately, each for a different line of manufacture. Railway running across the property, and Muskrat River bordering it. Price of entire property, $50,000.00.

The Town of Pembroke is situated at the junction of the Ottawa and Muskrat Rivers, and is favorably located between the East and West, being on the main line of three transcontinental railways.

Pembroke is a well-known lumbering centre, and has an abundance of raw material available for manufacturing purposes, such as pine, spruce, birch, maple, ash and poplar, which can be brought in by water and rail at a minimum of cost. Unlimited Hydro-Electric power obtainable at very low rates. There is a plenitude of labor available, both male and female. An unrivalled opportunity for an industry to start up with a small outlay.

For further particulars and plan of buildings, apply to

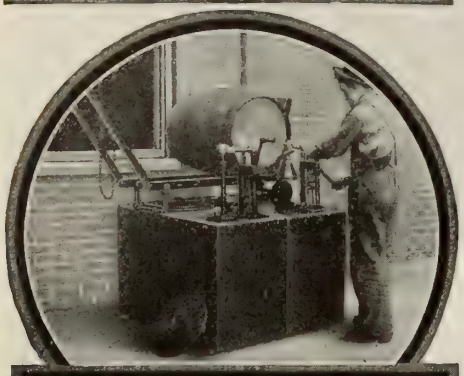
Tiresome, Expensive, Dangerous, Wasteful—but Unnecessary.



With Bowser Equipment One Man Does the Work with Less Time and Effort —and Without Loss.

STOP WASTING LABOR IN HANDLING OILS

Do away with the back-breaking, disagreeable labor in storing and handling oils.

With Bowser Storage Equipment the heavy work is done mechanically—there is no wasted energy—all oils are easily and quickly put into storage by gravity.

Save With BOWSER Systems

Distribution is done by accurate, rapid self-measuring pumps—no oils are left in shipping containers to dry up, leak and seep away—none is lost through spilling or dripping faucets. Every operation in the use of oils is done in a systematic, safe and saving manner.

Write us for literature, showing why Bowser Systems are a paying investment

A WALL RADIAL DRILL

That Puts Dollars in Your Pockets

Here's a real machine tool in the wall radial drilling line for your consideration. Listen to this—the machine is made of high grade materials throughout, and the workmanship is beyond criticism. It is designed with the particular idea of maximum production, at a minimum operating expense. Entire control within easy reach makes the operators "boosters" for these machines. You can keep the dollars that may be slipping away on your wall radial drilling propositions, in your pocket by the installation of this machine.

Springs *for* Every Use

We have been making springs of all kinds for 70 years. Let us advise you when in difficulty.

Tell us the purpose for which the spring is intended, and our experts will gladly co-operate to see that you get the design best suited to the purpose.

Dunbar Springs are thoroughly tested for **accuracy** and **quality.** Send us specifications, for estimates.

THE DUNBAR BROS. CO.

BRISTOL, CONN.

The Hammer With The Human Stroke

HEADS RIVETS COLD

Heads 'em tight or loose, flush, countersunk, or finishes heads any shape desired, and at the rate of:—

A rivet a second, sizes up to 3/16".
A rivet in two seconds, size ¼" to 3/8".
A rivet in three seconds, size 7/16" to 5/8".

And on special order we build machines to handle rivets up to 1½" with proportionate rapidity.

Built in eight sizes.

Besides riveting, the High Speed Riveting Hammer does all kinds of peining, swaging, upsetting, etc.

Send us sample assembly parts with rivets or sketch of your work,

and

Let us shoulder your riveting problems.
Send for the High Speed Hammer Book.

THE HIGH SPEED HAMMER COMPANY, INC.

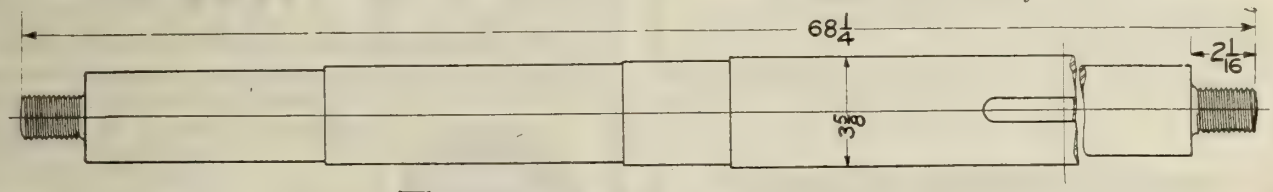
ROCHESTER, N.Y.

Smalley-General

THREAD MILLING MACHINES

Will give you a short cut to lower-cost thread milling.
Study the blue print and time study as given below.

MACHINE—Smalley-General Thread Miller No. 2.
THREAD—1½ in. diameter, 2 1-16 length, 6 pitch U.S. standard.
PIECE MILLED—Axle for tractor.
MILLING FEED—4.35 per minute.
MATERIAL—Machinery steel.



Tractor Axle Operation
TIME STUDY

5 minutes 37 seconds floor to floor milling both threads. Each thread milled in 65 seconds. Balance of time handling. Barker 3-jaw chuck used which had 12 in. unsupported overhang turn main spindle bearing to thread.

NOTE.—These parts were chucked through the rear end of main spindle. This was an awkward operation because the pieces were larger in the centre and the type of chuck would not let them through. A collet chuck with false collets would have permitted faster chucking.

Consult us on every phase of Thread Milling.

We will show you how to cut the costs.

Smalley - General Co., Inc., Bay City, Michigan

ARMCO IRON Welding Rods

OXY-ACETYLENE ELECTRIC

make *safe* welding easy

Armco Rods are 99.84 per cent. pure iron. No other fillers equal them in purity and uniformity of composition. Two kinds of rods of guaranteed analysis, one for electric and one for oxy-acetylene welding, do all the work (and better work) that formerly required many different compositions. Armco Rods flow freely, weld evenly, and give a joint that lends itself practically to all finishing operations. Send for booklet.

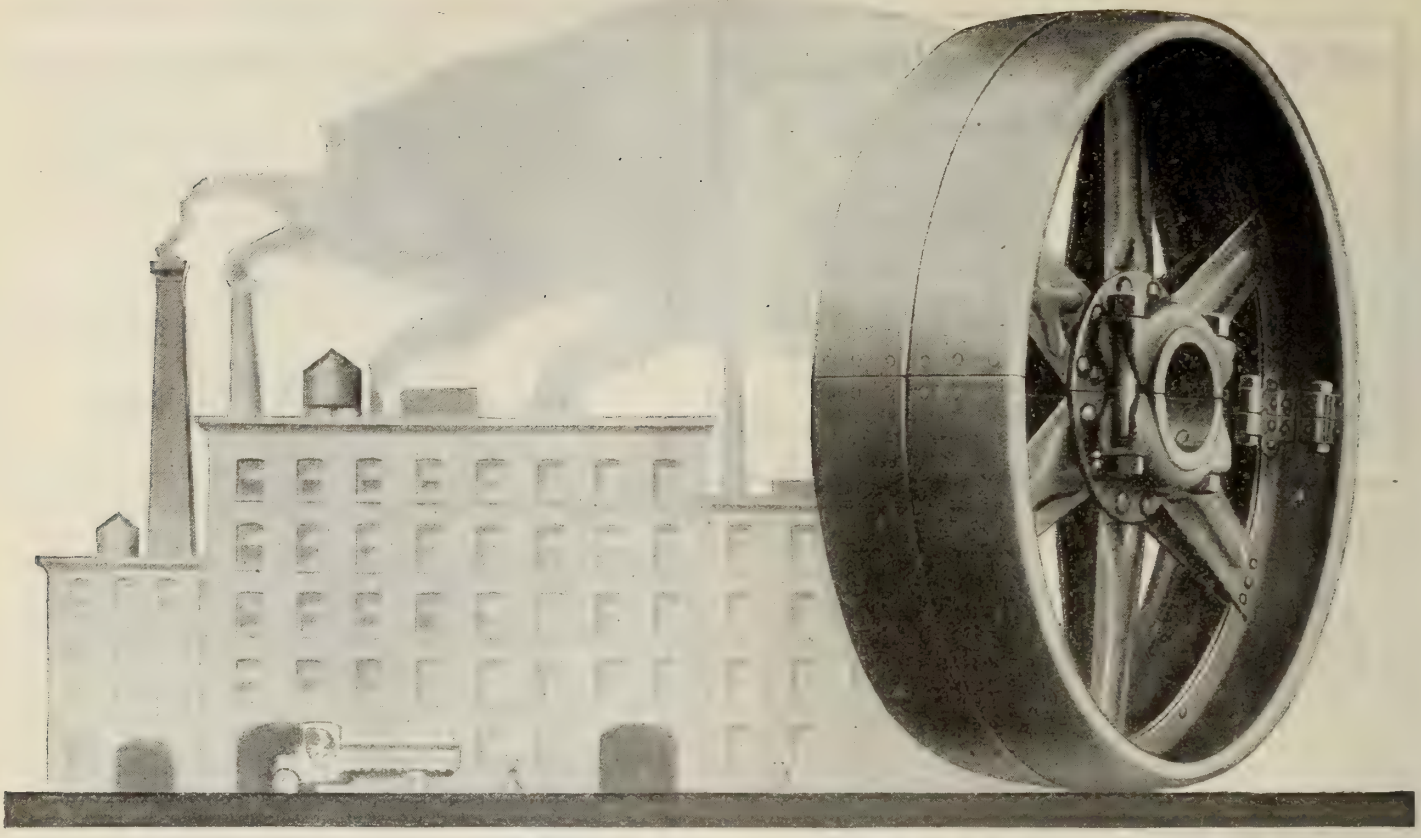
BRAZIL INDIANA USA



How Much Do You Lose Each Year Through Slipping Belts?

Many factories and mills are losing hundreds and even thousands of dollars a year through power losses and coal waste in the operation of their pulleys. This waste is due to belt slip and air fanning, which exists to an extent little recognized by the management.

AMERICAN STEEL SPLIT PULLEYS solve the problem of belt slip. They are guaranteed to reduce it to a minimum. They lengthen the life of the belt.

The face of the "American" Pulley has a high coefficient of friction and grips the belt. The sharp edges of the arms are constructed to cut the air and reduce air fanning to the lowest possible degree. The air groove in the face of the Pulley also helps to minimize belt slip.

American Steel Split Pulleys are manufactured to give maximum strength with minimum weight, check transmission losses and transmit power with great efficiency. They are guaranteed for double belt service and recommended for rim speeds up to 6,000 feet per minute.

NATIONAL DISTRIBUTION THROUGH SUPPLY HOUSES FROM PARENT STOCKS IN THE LARGER CITIES.

Our book, "Getting Maximum Pulley Efficiency," will tell you how to effect transmission savings. Sent free on request.

The American Pulley Company

Philadelphia, Pa.

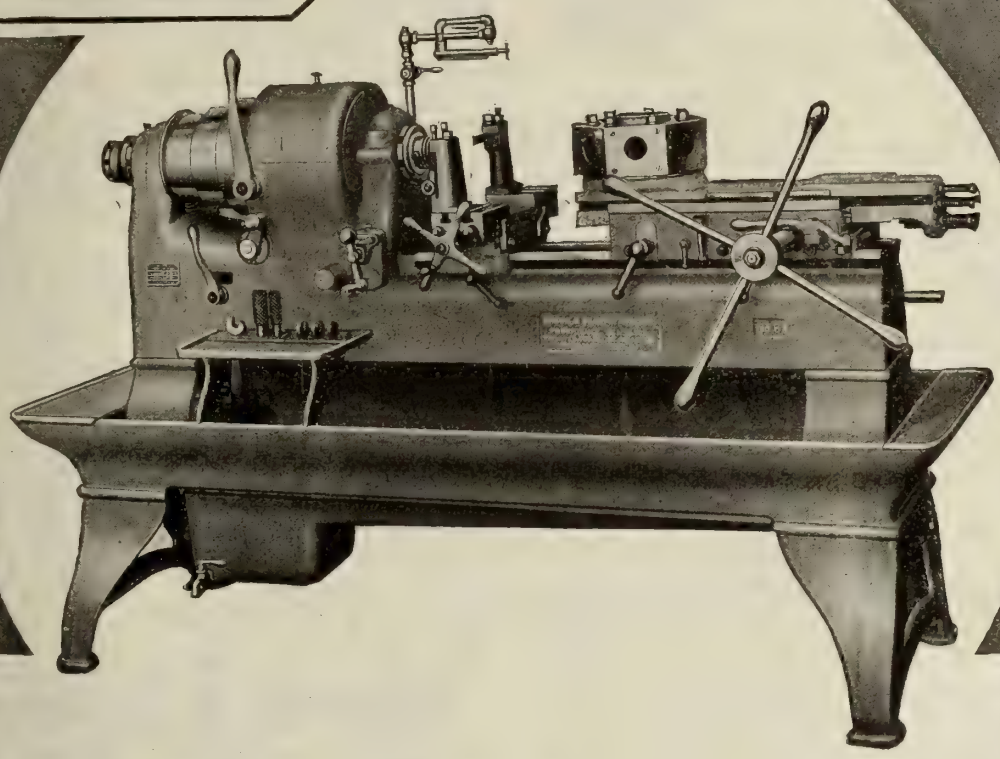
Brown & Sharpe
Plain
Screw Machines



No. 6

THE No. 6 Plain Screw Machine is one of the most popular machines in the modern shop. It is readily adaptable to the working of cast iron, machine steel or metals of this character.

The rugged design and wide range makes it suitable to a wide variety of work. The convenient location of all operating levers combined with independent feeds and speeds make it a primary support in keeping up production.

Let us tell you more in detail about

Brown & Sharpe Plain Screw Machines

Catalog 21-G features the big points.

Brown & Sharpe Mfg. Co., Providence, R. I., U. S. A.

Williams' "Agrippa" Tool Holders

TO keep pace with the rapid progress of the metal-working industries, speed—and hence economy—in production is essential. In modern shops, using heavy cuts and continuous high speeds, Williams' "Agrippa" Tool Holders meet the most exacting demands satisfactorily.

They are sturdy, dependable tools, the result of nearly half a century of experience in the specialized production of Superior Drop-Forgings, and are made in a wide range of sizes for all regular machining operations:—Turning, Boring, Planing, Threading, Knurling, Cutting-off and Side Work.

Our Booklet describes them fully—may we send you a copy?

J. H. Williams & Co.

UNION

POSITIVE DRIVE DRILL CHUCKS

The Union Drill Chuck is made in seven sizes (0 to 2 inches) with PATENT TRANSVERSE SLOT—so that drills with tenons can be inserted (see illustration). The shank of drill should be squared on two sides to enter the TRANSVERSE SLOT, giving a positive rotation to the drill independently of the jaws, permitting the jaws to centre and align the drill accurately. The drill is held absolutely true and will not slip under the hardest strain. This type of chuck will be found to give the best results on all classes of work from HIGH SPEED drilling to the hard BLACKSMITH and GENERAL REPAIR work.

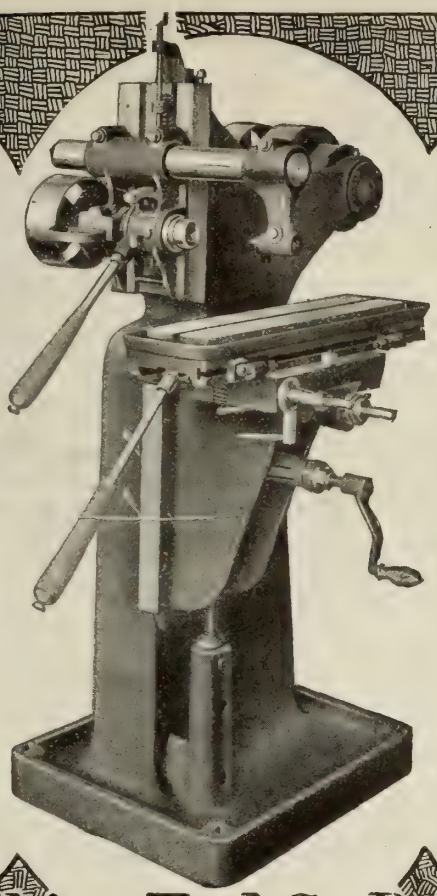
The "BRISTOL" Hand Milling Machine

Extensively used in the manufacture of small parts where accurate duplication is essential. Illustration shows our number 1 Heavy Type Hand Miller.

Specially designed for use on work where heavier machine than standard type is necessary.

BRISTOL



Convenience Assures Big Production

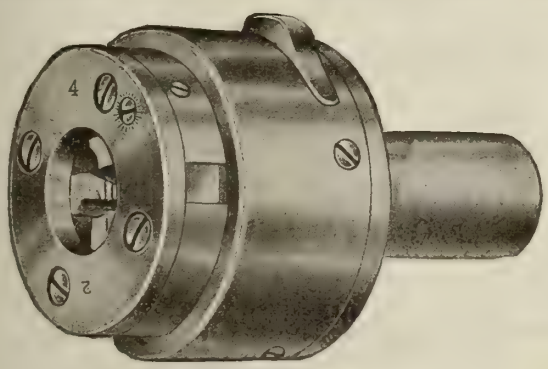
The lever controls make a very convenient method of operation, though crank is furnished for table feed for use when so desired.

Users acknowledge these machines to be exceptional producers, proving in many cases more satisfactory than milling machines of the more expensive type.

Write for catalogue.

BRISTOL

The Bristol Machine Tool Co. Bristol, Connecticut



H&G Die Heads

are of small outside diameter compared with the size of work they do.

The H. & G. illustrated is an automatic, self-opening Die Head designed especially for use on Gridley and National Acme Multiple Spindle Screw Machines and others that use the die in a revolving position. The four sizes of this Head cut up to 9/16", 1", 1¼" and 1½".

All parts are hardened and ground and interchangeable. In a word—it's an H. & G.

Positive Dependable Firm

Its superiority is no mere claim, it's a fact —proven by its record of service and satisfaction.

JACOBS MFG. CO. HARTFORD CONN. U.S.A.

Look at this again —closely

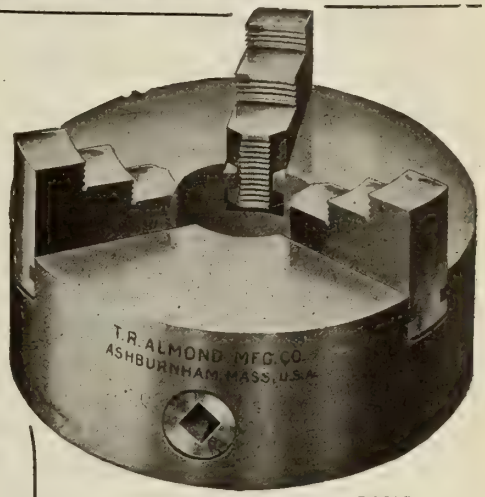
and read what we have to say below

WHEN a tap breaks off close or below the surface, you'll find the Walton Tap Extractor will save a great deal of time and trouble. The crucible fingers grasp the flutes of the tap, a twist of the wrench and the piece is out.
Don't you think it would pay to have a few lying around on your benches?

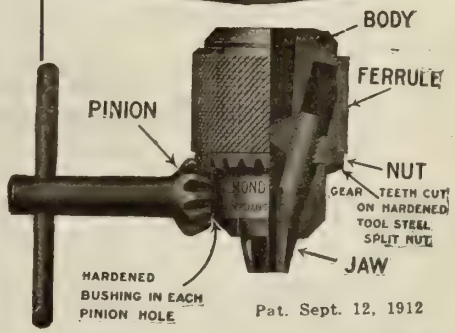
The Walton Company
Hartford, Conn.

ALMOND CHUCKS & MICROMETERS

Give them a try out. Universal Geared Scroll Chuck— Sizes 5", 6", 7½", 9" and 12".



Geared Nut Drill Chucks, in various capacities, 0" to 1".



Micrometer Calipers—

English Readings, 1", 2" and 3".

Metric Readings, 25, 50 and 75 m/m.

for

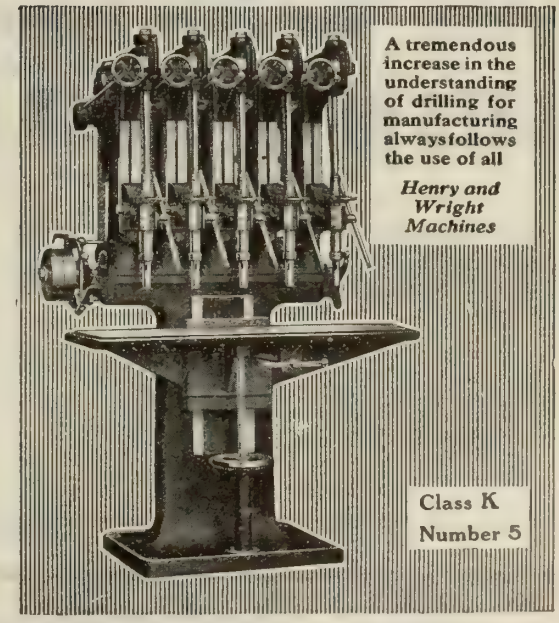
PRODUCTION

WE BUILD THEM BY HUNDREDS

Standardized Production enables us to offer this powerful Waterbury Grinder at such a low price. It grinds rapidly and accurately, all flat surfaces, dies, punches, planer, lathe, and other tools. Has adjustable table and tool rest with large radius of travel. Rigid, 3-point table supports giving great steadiness. A reliable, practical grinding outfit.

The Blake & Johnson Co., Waterbury, Conn.

HENRY & WRIGHT
Drilling Machines



A tremendous increase in the understanding of drilling for manufacturing always follows the use of all

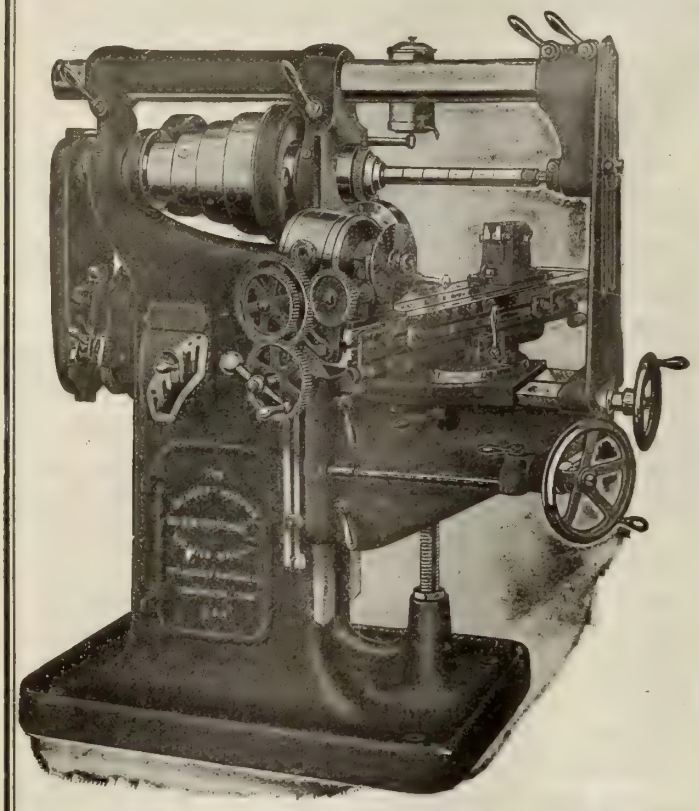
Anybody Can Operate This Miller



and Turn Out a Pile of Work so Simple to Operate is the

"HENDEY"

Skilled mechanics are scarce these days—but anyone can run a machine of its simplicity and turn out work accurately and fast without trouble.

All Feeds positive driven through gearings giving 18 changes.

This is the universal type—designed to handle all milling operations performed on machines of this character, either with regular equipment or by aid of attachments, which can be supplied for increasing efficiency and scope of machine.

FOUR FEATURES
OF THE
C.M.C. HEADSTOCK, on quick change geared lathes

(1) The three step cone double back geared drive permitting the use of extra wide belts and resulting in a strong drive combined with ample number of spindle speeds.

(2) The quick change gear mechanism which enables the operator to cut practically all the threads in every-day use without calculation or removal of gears.

(3) Our improved belt shifter which besides saving time forms a safety device preventing injury to the operator.

(4) Split phosphor bronze bearings with extra large oil chambers fed through large holes fitted with instantly removable plugs. No squirting with small oil cans through minute oil holes.

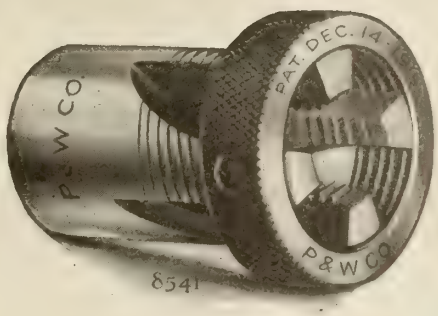
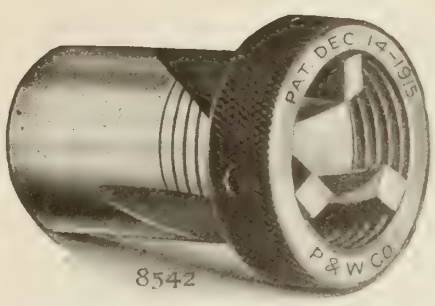
P. & W.

Spring Screw Dies and Hollow Mills



Spring Screw Die



Hollow Mill

Advantages of the Taper Thread Adjusting Collar

Ease and delicacy of adjustment to FINE LIMITS are secured without trouble and loss of time.

All lands or prongs of the die or hollow mill are adjusted in or out exactly the same amount by merely turning the collar, thus giving rise to the term CONCENTRIC ADJUSTMENT.

This concentric adjustment results in each land or cutting edge doing its proper share of work, and as a perfect circle is always maintained, accurate results are assured.

By having the bearings always on the point, there is no tearing while backing off, and the correct amount of clearance is obtained.

Write for 4-page descriptive Circular giving size and dimensions.

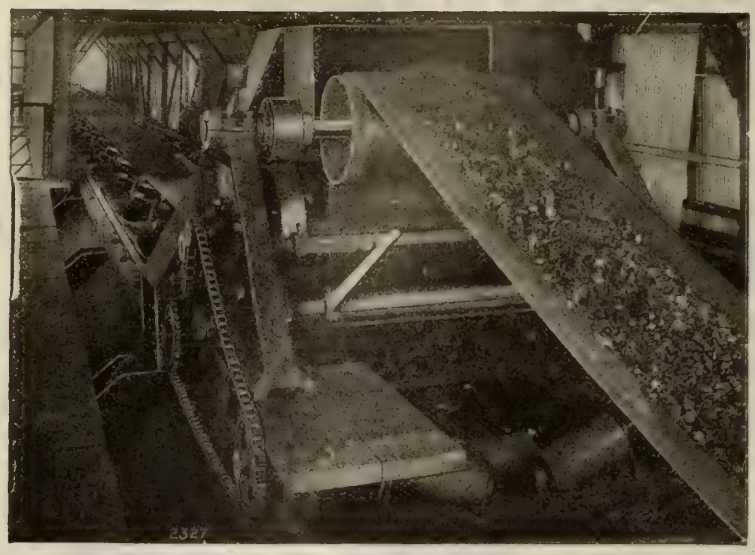
BELTING



SCANDINAVIA BELTING

HAVE you ever been disappointed in your conveyor belts by their opening up at the plies? This is one of the commonest reasons for failure in a conveyor belt.

Is there a remedy? YES. Buy a belt that is not built up in plies. Such a belt is

Scandinavia Belting

This is a solid woven belt, made of long stock cotton, and it is built to wear. We have just had reports from two large users saying that Scandinavia Belting gives them more dollars in value for handling materials than any other belt they had ever used.

Use it for conveying

Purchase the Products of Canadian Mills

TO uphold the Glory we have jointly earned—to honor our noble dead—to comfort the wounded, and extend to the men returned the hand of prosperous welcome, we must cast aside all forebodings and face the future with unbounded courage and confidence and, without a shadow of doubt, declare to the World that this Nation, which was so quickly and successfully transformed to a War basis, can be depended upon to revert to Peace conditions with equal success. The buyer and seller must recognize their duty to the Nation and co-operate fully to the end that all products that can be produced in Canada by Canadian workmen shall not be purchased elsewhere.

OUR Duty is plain; Canada with Canadian labor and capital can produce, manufacture and distribute products sufficient to keep the wheels of industry turning to the limit. The song of Prosperity and Happiness should ring out all over the land. Let us sincerely pledge to the extent of our needs, to purchase materials produced in Canada by Canadian Workmen, and the result of our efforts will return to us the Blessings of a Prosperous and Happy Nation.

ANNOUNCEMENT

THE ALGOMA STEEL CORPORATION, LIMITED, take pleasure in announcing to their customers and the Canadian trade that in accordance with the widespread desire throughout the Dominion that there should be obtained in Canada with Canadian labor, a much larger proportion of the requirements of this country in STEEL SECTIONS for STRUCTURAL PURPOSES, CAR CONSTRUCTION, SHIPBUILDERS' REQUIREMENTS, etc., they are just completing extensive alterations and additions to their rolling mills, and on or about 1ST NOVEMBER, will be ready to produce and ship American Standard Sections of BEAMS and CHANNELS up to and including 15″, all standard sections of ANGLES from 6″ x 6″ down to 1¼″ x 1¼″, ZEE BARS for car builders and general purposes, small and large ROUNDS and SQUARES, and FLAT BARS up to 14″ wide. The quality of the product is already well known to the trade, and is exclusively steel made by the Open Hearth process. and can be furnished in all grades from the softest rivet stock to high carbon special spring material. Motto: "Quality and Service."

MARK OF ALGOMA O.H. QUALITY

The following are the sections which will be rolled:—

ANGLES—Equal Leg—
6 x 6″—5 x 5″—4 x 4″
3½ x 3½″—3 x 3″
2½ x 2½″—2¼ x 2¼″
2 x 2″—1¾ x 1¾″
1½ x 1½″—1¼ x 1¼″

ANGLES—Unequal Leg—
6 x 4″—6 x 3½″—5 x 4″
5 x 3½″—5 x 3″—4½ x 3″
4 x 3½″—4 x 3″—3½ x 3″
3½ x 2½″—3 x 2½″—3 x 2″
2½ x 2″

BEAMS—
15″, 12″, 10″, 8″, 6″, 5″, 4″, 3″.

CHANNELS—
15″, 13″, 12″, 10″, 8″, 6″, 5″, 4″, 3″.

ZEES—
3¼ x 5 x 3¼ x 5 x 5/16″
3 5/16 x 5 1/16 x 3 5/16 x ⅜″
3⅜ x 5⅛ x 3¾ x 7/16″
3 1/16 x 4 x 3 1/16 x ¼″
3⅛ x 4 1/16 x 3⅛ x 5/16″
3 3/16 x 4⅛ x 3 3/16 x ⅜″
2 11/16 x 3 x 2 11/16 x ¼″
2¾ x 3 1/16 x 2¾ x 5/16″

ROUNDS—
All sizes from ½″ up to and including 4″.

SQUARES—
All sizes from ½″ up to and including 3″.

FLATS—
All sizes from 1 x ¼″ up to and including 14″ wide.

MINE RAILS—
All sections from 12 lbs. up to and including 45 lbs. per yard.

PIG IRON—
Machine Cast Foundry, Maleable and Basic.
Sulphate of Ammonia.

NITRE CAKE.

For the better convenience of customers who may find it necessary to secure rush shipments of particular items, they contemplate keeping a large stock of all the various standard sections constantly on hand, and to this end extensive warehouse facilities are being prepared.
Your enquiries and business will be appreciated.

SPEED UP THE WORK

Rising costs are knocking the bottom out of profits these days! Materials and labor are up. No chance to reduce them. But you can speed up your work. The Hoefer Manufacturing Company has a proposition that will cut your drilling cost. Not guesswork, either, but on a basis proved by experience.

By using Hoefer Auxiliary Heads you can drill ten, twelve or more holes in the same time as one. Not only do you save the drilling time, but also the time lost shifting the jigs and raising and lowering the spindle for the extra holes.

360 manufacturers, 99 distinct lines of business—probably some of your competitors—employ Hoefer Auxiliary Heads to increase profits. They say the Hoefer Auxiliary Heads pay for themselves in 30 to 60 days.

Hoefer Auxiliary Heads are made in any multiple, arranged in any manner, from 2 up. Made by expert toolmakers and guaranteed to handle accurately the work for which they are designed.

Investigate now. Stop the leakage of dollars due to the use of single drills. Write for catalog and send blueprint of some of your work for estimate of time and cost.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25%; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood pattern-makers who are able to make any changes that may commend themselves to you.

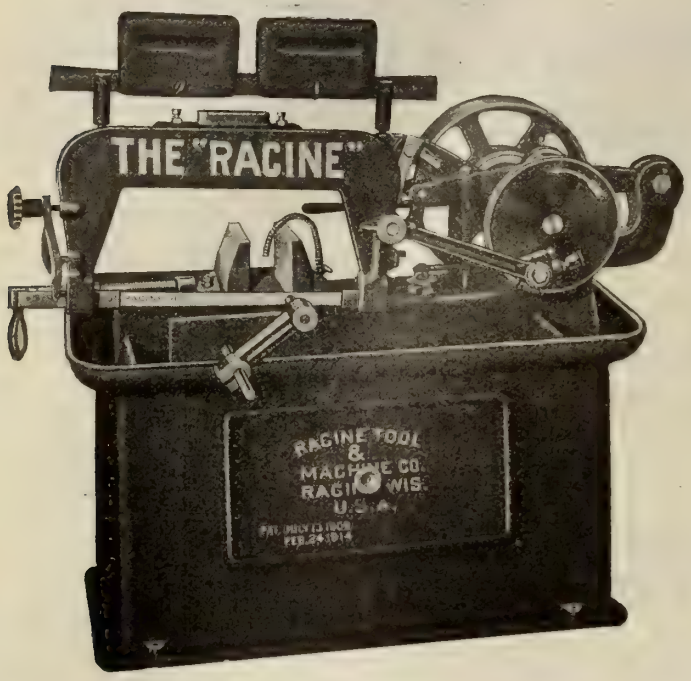
If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.
We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us.

ASK US

Standard the World Over

"THE RACINE"



HIGH SPEED METAL CUTTING MACHINE

Reduces Blade Expense

Aside from its ability to turn out more work than any other metal cutting machine, "THE RACINE" will save you considerable money on blades alone—enough to pay for itself in a reasonable time. The automatic lifting device is responsible for that. It automatically raises the blade on the return stroke, relieving it of all dragging or strain. This also means quicker cutting, less power used and greater production.

There are many ways "THE RACINE" will prove a big saving. Let us tell them to you.

RAWHIDE OR METAL

Announcing the

International Machinery Exposition

This Fall in Grand Central Palace, New York, there will open the most advanced enterprise in the Machinery Industry announced since the signing of the Armistice.

This huge INTERNATIONAL MACHINERY EXPOSITION, which will occupy 50,000 square feet of floor space in the largest exhibition building in existence, will be a remarkable permanent display of all that is most modern and best in the great production machinery industry. Included in it will be displays of the most modern engines, lathes, milling machinery, planers, drills, screw cutters, awl presses—boring, can-making, wood-turning machines, etc. It will be one of the eight or more permanent expositions operated by the Merchants and Manufacturers Exchange of New York in this largest of exhibition buildings.

Thousands of manufacturers, buyers, purchasing agents, dealers, jobbers, engineers and others from all over the globe will visit the Machinery Exposition in this great trade mart. The buying power of these visitors will run into billions of dollars. There has been an urgent need for a long time for just such a permanent exposition.

The Nemours Trading Corporation, which controls the Merchants and Manufacturers Exchange of New York, operating Grand Central Palace, has representatives in every city of commercial value on the globe—19 branch offices, 3,000 foreign selling agencies. The commercial connections that exhibitors will find possible to make through this organization will be invaluable.

Here is your opportunity to place *your* product before the eyes of the world's dealers and purchasing agents—and to obtain the cumulative benefit of reaching by *direct contact* thousands of buyers. An impressive display here will cost about one-tenth the expenses of *one* traveling salesman. October 15th is the opening date.

Make This Great Trade Mecca—Grand Central Palace—Your Salesroom For World Trade. For Further Information Address

H&G Die Heads

are of small outside diameter compared with the size of work they do.

The H. & G. illustrated is an automatic, self-opening Die Head designed especially for use on Gridley and National Acme Multiple Spindle Screw Machines and others that use the die in a revolving position. The four sizes of this Head cut up to 9/16", 1", 1¼" and 1½".

All parts are hardened and ground and interchangeable. In a word—it's an H. & G.

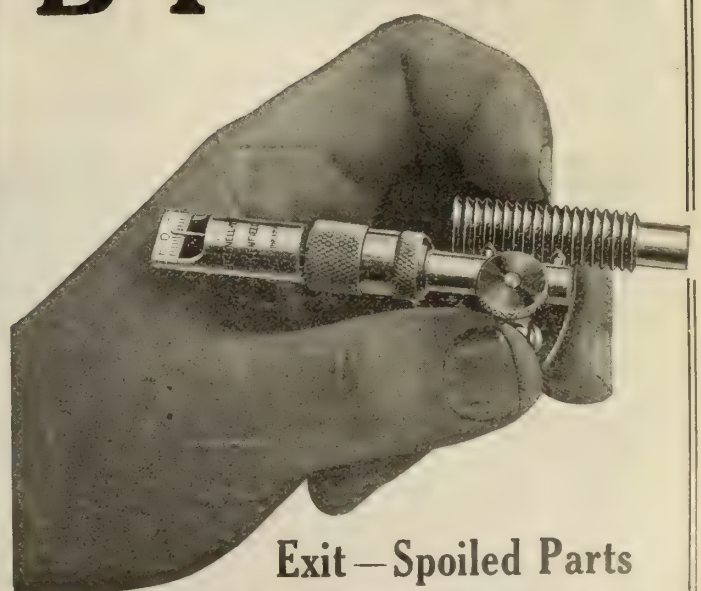
B-T THREAD LEAD INDICATOR



Exit—Spoiled Parts

Did you ever have to scrap a threaded part because of incorrect measurement in lead? Were you ever forced, during a rush job, to thread a part over again, because it didn't fit as it should?

B-T THREAD INDICATORS

enable you to get the right thread lead instantly and maintain a constant check upon it. They will detect errors of one thousandth of an inch—can be used for testing add and even pitches, as well as internal and external threads.

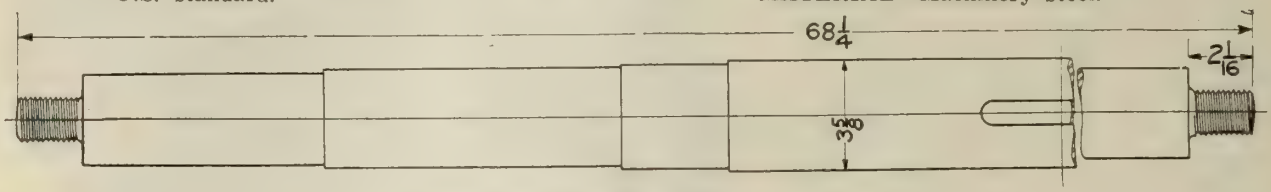
Smalley-General

THREAD MILLING MACHINES

Will give you a short cut to lower-cost thread milling.
Study the blue print and time study as given below.

MACHINE—Smalley-General Thread Miller No. 2.
THREAD—1½ in. diameter, 2 1-16 length, 6 pitch U.S. standard.
PIECE MILLED—Axle for tractor.
MILLING FEED—4.35 per minute.
MATERIAL—Machinery steel.



Tractor Axle Operation
TIME STUDY

5 minutes 37 seconds floor to floor milling both threads. Each thread milled in 65 seconds. Balance of time handling. Barker 3-jaw chuck used which had 12 in. unsupported overhang turn main spindle bearing to thread.

NOTE.—These parts were chucked through the rear end of main spindle. This was an awkward operation because the pieces were larger in the centre and the type of chuck would not let them through. A collet chuck with false collets would have permitted faster chucking.

Consult us on every phase of Thread Milling.

We will show you how to cut the costs.

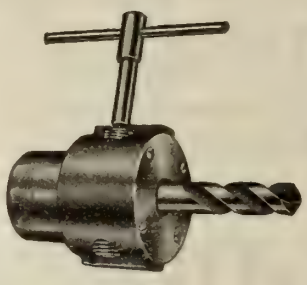
UNION



POSITIVE DRIVE DRILL CHUCKS

The Union Drill Chuck is made in seven sizes (0 to 2 inches) with PATENT TRANSVERSE SLOT—so that drills with tenons can be inserted (see illustration). The shank of drill should be squared on two sides to enter the TRANSVERSE SLOT, giving a positive rotation to the drill independently of the jaws, permitting the jaws to centre and align the drill accurately. The drill is held absolutely true and will not slip under the hardest strain. This type of chuck will be found to give the best results on all classes of work from HIGH SPEED drilling to the hard BLACKSMITH and GENERAL REPAIR work.

Notes On Grinding

NORTON COMPANY. WORCESTER, MASS.

No. 64A

Semi-Steel

The composition and physical properties of semi-steel are not generally understood, and this often leads to difficulties in selecting proper grinding wheels. Semi-steel is a cast iron alloy and must be classed as cast iron, although it is really of a little higher grade and somewhat stronger than ordinary gray iron. Table 1 will show its chemical properties as compared with those of gray iron.

TABLE I.

Analysis of Gray Cast Iron and Semi-Steel.

	Silicon %	Graphite %	Combined Carbon %	Total Carbon %
Gray Cast Iron	2.00	3.10	0.30	3.40
Semi-Steel	1.75	2.80	0.40	3.20

Although semi-steel could undoubtedly be made from materials which are commonly used for cast iron, it is practically always produced by charging with these a certain amount of steel scrap to bring total carbon desired.

Because steel has a higher tensile strength than cast iron, many have inferred that it was the steel addition which made semi-steel stronger than the ordinary gray cast iron. The rather unfortunate name, semi-steel, apparently was given because of the steel used and the intermediate strength which the resulting product possessed. However, during the melting down of the charge the steel scrap becomes molten and its constituents merge with those of the other iron material charged.

The physical properties of the steel which have been used in the mixture have been entirely obliterated during the melting process. You will note from Table 2 that the tensile strength of semi-steel is increased somewhat over gray cast iron, but that it is still far below that of cast steel. Its weakness under shock is also shown in the number of blows required to break a bar of given size. Its resistance to shock is only a very little greater than cast iron, only half as much as malleable cast iron, and one-eighth as much as cast steel.

TABLE II.

Alloy,	Tensile Strength lbs. per sq in.	No. of Blows to Break.
Cast iron (gray)	23,400	7
Semi-steel	35,050	11
Mall. cast iron	37,140	22
Cast steel	72,120	92

This places semi-steel quite definitely in the cast iron class, and CRYSTOLON wheels will be found more efficient generally than wheels composed of regular ALUNDUM. In a few cases, however, regular ALUNDUM and No. 66 ALUNDUM have been used to good advantage on semi-steel piston rings and such articles.

The Use of the Crane in Modern Industry

Various Illustrative Examples of Crane Installations as Adopted in Various Lines of Industry. Without These Most Necessary Aids in Speeding Up the Work, We Would Be in a Sorry State

By J. H. MOORE, Associate Editor Canadian Machinery

TO thoroughly cover the field of usefulness of cranes in the industrial world would take a volume, but we will, in a brief way, discuss this subject, more by illustrations than by words, for after all, pictures will bring to the eye far better than written description could ever do the wide variance of their uses.

The Chain Block

Let us first consider the chain block. Of course we will not attempt to say that the chain block is always the most suitable device, but there is many a case where a chain block is the best possible solution to your handling problem.

A properly-designed chain block will perform a great number of lifting oper-

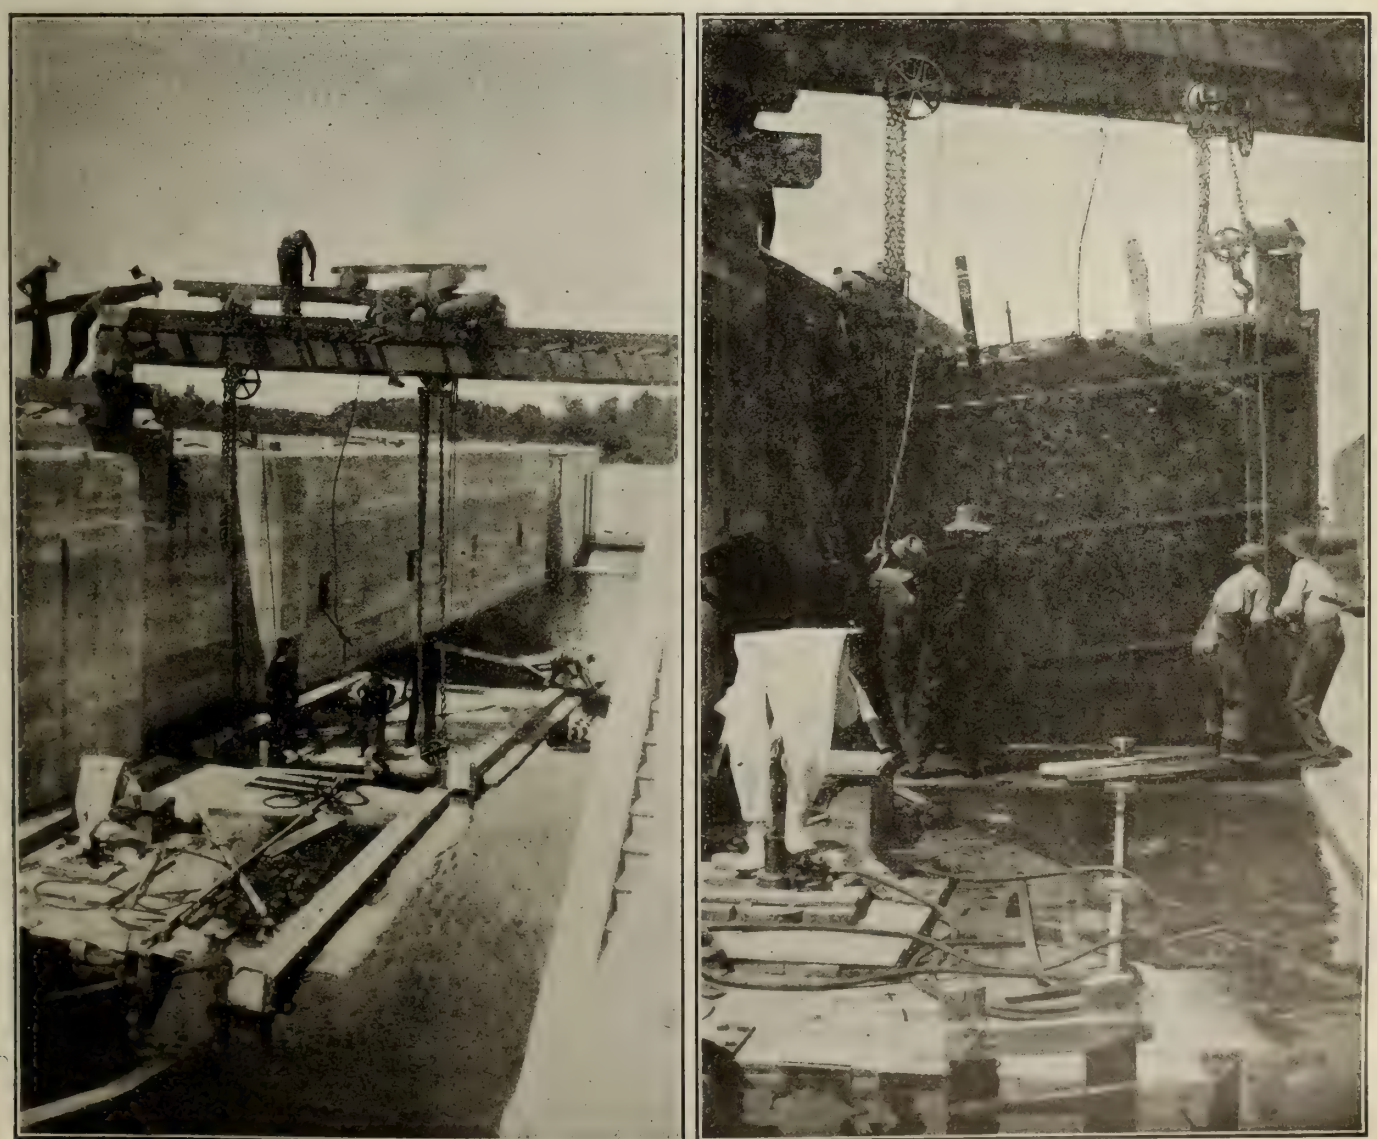

FIG. 1.—A VIEW SHOWING HOW TWO 10-TON MORRIS WORM-GEAR CHAIN BLOCKS WERE USED ON CONSTRUCTION WORK.

ations with very little capital investment, and when the chain block is carefully manufactured the operating expense will be reasonably small.

There are various styles of these chain blocks, one of which is the worm-gear design. This type is a light rugged hoist, very popular among contractors, erectors, and constructional men generally, because it is easily handled and will withstand a great deal of rough usage. Where there is any danger of a load coming suddenly on the hook, such as the slipping of a heavy piece, this as a particularly suitable type of hoist, especially when fitted with a shock absorber.

In capacities of ten to sixty tons the worm-gear chain block is superior to any other type. The worm and worm wheel reduction lends itself admirably to obtaining the high purchase necessary to lift a heavy weight without the use of an excessive number of sheaves and falls.

Spin Gear Blocks

This type of block is already well known for its general efficiency. For regular day-to-day service this type of block is ideal. A machine shop without a few of these blocks installed is like a boat without water to float it—not of much account.

Then there is the triple gear chain block, and the gravity-lowering chain block. These are all, so to speak, offshoots of the former, and each type accomplishes its own particular purpose. So now, since we have briefly discussed these various types let us see some of them in actual use.

At Fig. 1 we illustrate two 10-ton worm-gear chain blocks on construction work. The particular work being done is that of lifting into position the ponderous lock gates of the Severn Canal. This operation, without the use of blocks of this nature would indeed have proved a difficult task, but as arranged the job was a very easy one.

The Machine Shop

The use of spur-gear chain blocks in the machine shop is not as common an occurence as it should be.

It stands to reason that if a workman cannot handle his work easily his movements will be slow and clumsy. Should the lifting part be very heavy, he soon acquires a distaste for his work, and thus production suffers.

A scheme to help the workman accomplish better and quicker work is shown in Fig. 2.

Here we illustrate how the operator at the grinding machine can be relieved of considerable labor by means of a spin-gear chain block.

The Overhead I-Beam System

By the use of overhead I-Beam runways, further advantage to the shifting and lifting problem is obtained. To state all the uses where I-beams can be used is impossible, for practically every condition imaginable lends itself to this method. For example, let us take two widely different examples. A certain firm which were dipping a considerable amount of steel sashes, installed an overhead I-beam system, with the necessary curves, etc, and in conjunction with this installed a small air hoist. Their production soared beyond even their most sanguine expectations after this installation.

The other installation was in a certain warehouse where the overhead system was placed in operation. It was desired that only a single track be laid, or rather hung, as the I-beam is suspended from

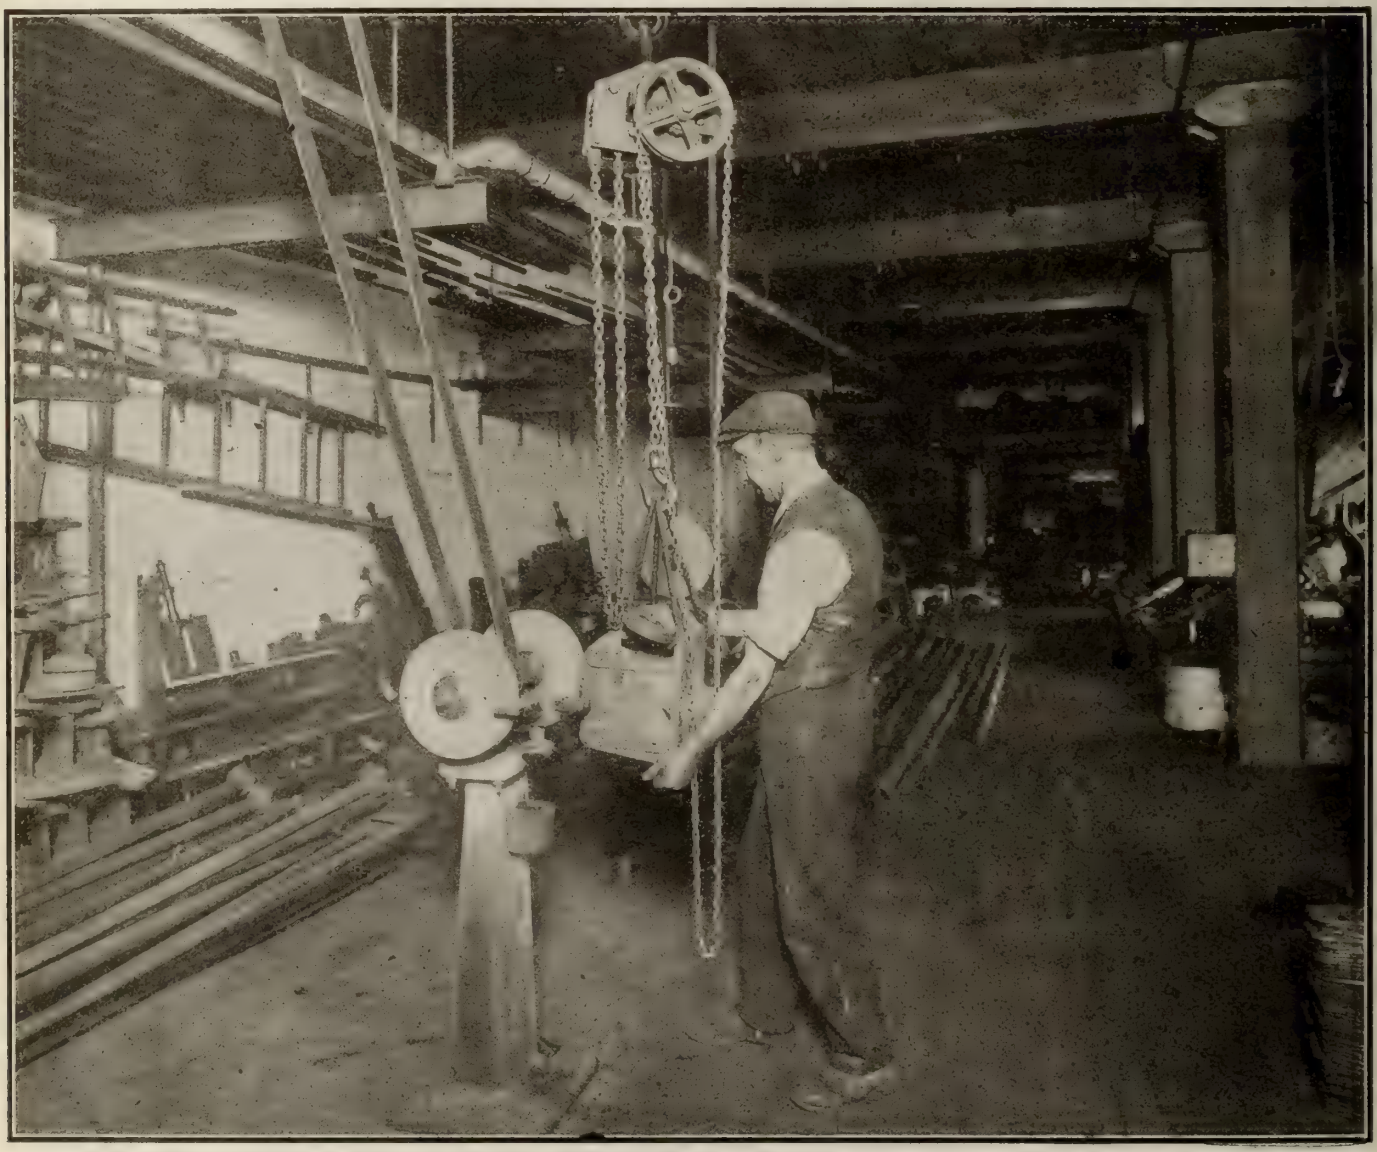

FIG. 2.—USING THE MORRIS SPUR-GEAR BLOCK AT THE GRINDING WHEEL.

the ceiling, and yet it was often quite necessary that men pass each other with loads. A by-pass was installed with splendid success, and the problem, if such we could call it, was solved without effort.

The advantages of this overhead system are without number, for by means of switches, by-passes, etc., you can practically run your crane system to every accessible corner of the plant.

Post Jib Crane

A crane of great service in the foundry or forge shop is that of the jib crane. At Fig. 3 is shown a typical installation of a jib crane, used to lighten labor and speed production at the steam hammer.

The crane used is of the V10 type, with a capacity of two tons. The freedom of action which this crane affords is easily seen, and on work of this nature cannot be excelled. It tends to make satisfied workmen and increases production to a remarkable extent.

Another place where jib cranes can be used to good advantage is at the shipping platform of the smaller shop.

The Overhead Crane

Last, but not least, we show the heavier style of hand-operated overhead crane. In an engine room such as shown, an installation of this nature is absolutely essential. The 30-ton type G crane, as it is called, has a span of 68 feet, and has twin lifting gears. With an equipment such as illustrated, should any repairs or lifting be necessary, you have to hand the means of easily accomplishing your desire.

As a summing up we can safely say that cranes fill a much felt want in the industrial field, and by a careful study of how they had best be installed we open up the way for increased production and better satisfied employees. The various illustrations throughout this article were kindly loaned us by the Herbert Morris Crane and Hoist Company, of Niagara Falls, Ont., who are well known in the crane industry of to-day. Of course it is absolutely impossible to show even a small portion of the various installations as placed by this firm, but we have at any rate brought out the importance and necessity of this type of shop equipment.

It was recently stated in a French journal that the necessity of purchasing foreign coal might be relieved by developing the water power of France, which is estimated at 10,000,000 horse-power, as compared with 7,000,000 horse-power for Norway and 6,000,000 horse-power for Sweden. Before the war only about 750,000 horse-power was used, but a further 450,000 horse-power was developed during the war, and by the end of 1921, 1,600,000 horse-power, or 16 per cent. of France's resources, will be worked. This leaves a huge amount of water power in reserve, and, in addition, there are large potential resources in the rivers of Indo-China and French West Africa. One million water horse-power would lessen the consumption of coal for power production by at least 3½ million tons, costing about 300 million francs, and the comparison is the more striking when it is remembered that a hydro-electric installation has eight times the average efficiency of steam engines.

A copper alloy said to have the hardness of steel and of great tensile strength has been successfully experimented upon in France. It consists of 1 lb. each of chromium and aluminum, and adding 22 lbs. of copper, 5 lbs. of nickel and 4 lbs. of zinc, with intervals of between half an hour and an hour between the successive

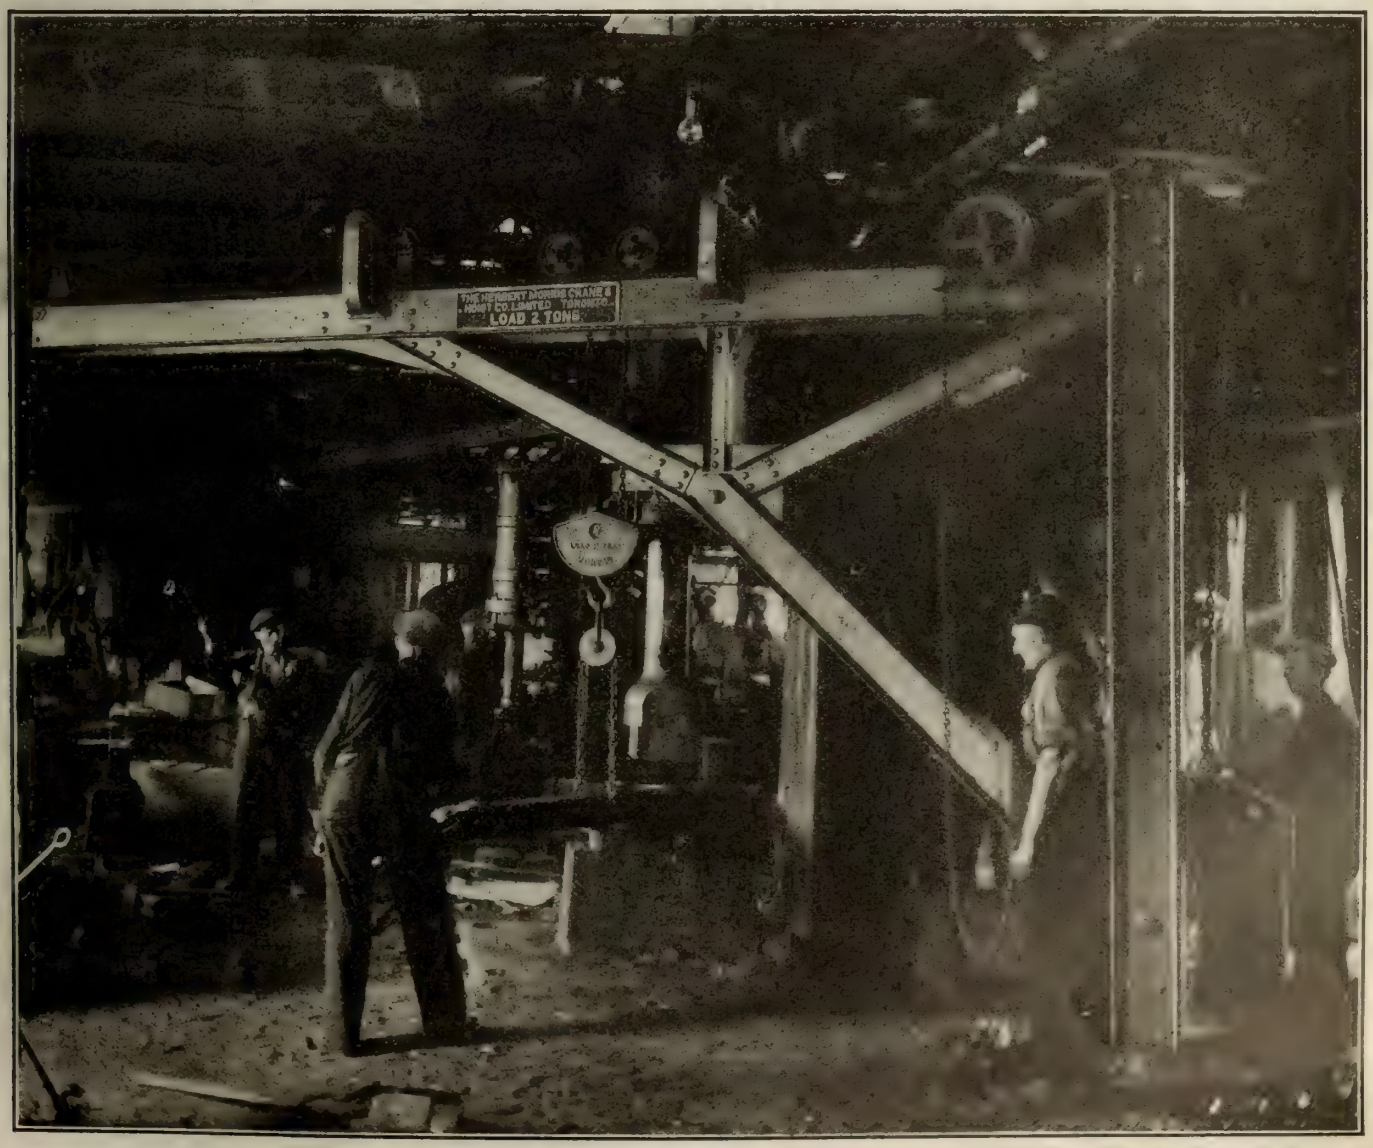

FIG. 3.—TYPE U10 MORRIS JIB CRANE SERVING STEAM HAMMER

additions to the fused mixture. By varying the proportions of chromium and copper the alloy is said to give a considerable range of properties, with adaptation to many uses.

Where asbestos and some other materials are utilized for gaskets, they are apt to stick to the metal and upon overhauling must be scraped off. This means making new members and a loss of time and a source of expense. A tight fit may be made by rubbing the packing and metal parts with dry graphite, which is not affected by heat and will allow the gaskets to be removed as a whole.

Everybody knows how hard it is to pour graphite from any ordinary container without having it spill or come out too fast and make everything black. If the graphite is put in a discarded tooth-powder can (the kind with the regulating slot in the top) not only can its flow be regulated but it is kept clean and dry.

To preserve drawings, wash the drawings well with a solution of isinglass. Prepare another solution by dissolving 1 oz. of Canada balsam in 2 oz. of best oil of turpentine. Coat the drawing with this, using a camel's hair brush to obtain an even surface.

Asbestos is a Greek word, meaning "unquenchable," but used in the sense, "inconsumable." It consists of silicon magnesia and lime of pyroxene. It was woven into cloth by the Greeks for wrapping dead bodies when they were burned in the funeral pyre that the ashes might be preserved. In ancient times the lamps that were always kept burning in the temples had wicks made from asbestos fibre. For many years after the revival of industrial activity asbestos was little used in the arts, and it is only recently that its usefulness has been fully recognized.

If a little potassium chloride is added to glue, it will tend to prevent cracking or peeling when exposed to heat.

The hardness of water is usually expressed in degrees, one degree being equivalent to a solution of one part by weight by carbonate of lime or other hardening salts to one hundred thousand parts of water. Wells generally contain the hardest water, 35 degrees of hardness being common. With water of one degree of hardness, the water contained in a single big tender would deposit 75 lbs. of mud or scale-making sediment.

Wash the files in warm water to remove the grease and dirt, then wash in warm water and dry by heat. Put 1½ pints of warm water in a wooden vessel, put in the files, add 3 ounces of blue vitriol, finely powdered, and 3 ounces of borax. Mix well, and turn the files so that every one may come in contact with the mixture. Add 10½ ounces of sulphuric acid and ½ ounce of vinegar. Remove the files after a short time, dry, rub with olive oil, and wrap in porous paper. Coarse files should be kept in the mixture for a longer time than the fine ones.

An Italian metallurgist, C. Rossi, of Legano, claims to have produced an acid-proof iron alloy by melting pig iron and ferro-silicon in an electric furnace with a small amount of iron sulphide as flux. The alloy contains from 13 to 21 per cent. of silicon.

FIG. 4.—A 30-TON TYPE "G" CRANE, 68-FT. SPAN, WITH TWIN LIFTING GEARS, AS INSTALLED BY THE MORRIS CO.

The Various Mechanical Properties of Steel

Taking Up the Consideration of the Question of Brittleness, Together With Investigation of Failures of Various Kinds. A Paper of This Nature on Steel is Especially Valuable at the Present Time

By W. H. HATFIELD, D. Met. of the Brown-Firth Research Laboratory, Sheffield, Associate Member

(Continued from last issue)

THE wide variation in values obtained certainly point to indication being obtained of some intrinsic merit of the material.

In the author's opinion, the Stanton test or some modification of it, in which the force of the blow is capable of being varied with the elastic range of the steel, seems to be capable of offering much useful information to the engineer. This test is one which certainly does approximate to the conditions existing in some slightly over-stressed parts. The values obtained are influenced apparently chiefly by the magnitude of the elastic range, and are not much influenced by notched-bar brittleness; neither do they appear to be influenced by that property in the materials which are brought out in the Arnold and Sankey test. The elastic range is not, however, the only determining factor. In making these comments, it is only fair to state that the author has hitherto only employed the standard conditions laid down for this test in the Appendix. In support of the Stanton method the whole of the experimental work of Wöhler draws us to the same conclusion. The author has much sympathy with the view expressed by Stanton and Bairstow,* when they say: "For determinations of resistance to shock under approximate working conditions, the test should be one in which the energy absorbed in plastic deformation is at a minimum, since plastic deformation has little relation to its construction value." Single-blow impact tests do not afford sufficient information for the engineer, and the author feels that he has provided data in this paper sufficiently conclusive to indicate that such single-blow impact tests, depending as they do upon the energy absorbed in plastic deformation above the elastic limit, yield insufficient and probably no data as to the elastic range, and the behaviour of the material within that range.

There are no doubt concrete cases where each test will provide data of particular service in some field of engineering; and the careful study and selection of the tests to be employed in each field merits, and will repay the most careful attention of the engineer. This paper has dealt with the response of different steels to the more simple forms of test. An examination of the nature of the stresses acting on various parts of machines and structures will indicate that in many cases the stresses are not of a simple character but are combinations of tension, compression, shear, etc. To the designer who wishes to create a reasonably safe design, and at the same time to economize and get the most out of the material employed, a knowledge of the behaviour of the material under these complex stresses is important. Much interesting work has been done in investigation of the effects of such stresses, notably by Guest, Hancock, Mason, Scoble, Smith and also by A. J. Becker, of the University of Illlinois. The presence of a second stress at a given point in the material, in a direction at right angles to the first, modifies the response of the material to the first stress, as would be expected. To the author it appears that a complete experimental study of all the different combinations of stresses likely to be met with in practice carried out on all those materials of construction likely to be employed, would constitute a work of far-reaching value to engineers.

*Proceedings, I. Mech. E., 1908, page 889.

Impact Tests

There are obviously many instances in which it is expedient that steel shall be stressed beyond its elastic limit, and, therefore, in such instances, some knowledge of the behaviour of the material under impact tests is generally considered instructive. Various types of tests have been devised, all with the purpose of measuring the relative brittleness of metals. They include impact-bending tests, impact-tensile, and impact-crushing tests. The author's remarks are intended to apply chiefly to those tests described in Appendix I. In all these impact tests the value obtained is essentially dependent upon the energy absorbed by the material in plastic deformation, and the experimental work by different investigators has generally been with a view to determining the factors which affect this absorption of energy. During recent years much progress has been made. For instance, it is now definitely established that the properties of the material as shown by the static tensile tests, that is, elastic limit, yield, ultimate stress, elongation and contraction of area, fail at times to reveal differences brought out under the notched-impact tests. It is generally established that, everything else being equal, the harder the material the smaller the energy required to produce rupture under the notched-impact tests. There are, however, instances where steels of the same hardness give widely different values under the impact test, and in some such instances the tensile test and, for that matter the microscope, utterly fail to give any indication of the difference in the material. It is in this respect that the Izod, Charpy, and such impact tests given information of interest. Two pieces of the same steel may be hardened and tempered to have similar tensile properties, and yet have widely dissimilar properties under the notched-bar impact and notched-bar slow-bending tests. Much work has been done in this direction by a number of investigators, but a complete and valuable treatise on this subject was presented by Captain Philpot some months ago.* In this paper, Philpot confirms the earlier work of Stanton and Bairstow,† indicating that the shock in the test is not the determining factor, and shows that the type of notch is essential. He records a number of interesting experiments in which notched bars are broken under a static load and such disparities in values as are obtained under the Izod notched-bar impact tests are equally well brought out when the load is slowly applied. His experiments also clearly indicated that up to, and for some considerable distance beyond, the range of pro-

portionality, the behaviour of the two steels was identical. These facts are of fundamental importance to engineers.

The influence of the shape of the notch has been very thoroughly investigated, and it is clearly shown that with increasing sharpness of notch the discriminating value of the test is increased. As an instance of the comparative effect of the shape of the notch, it may be pointed out that the Charpy test with a 2-3 mm. radius, shows a much less disparity in the materials in unlike condition than does the Izod test; a reference to Fig. 5 (page 618), which contains the results of the Izod and Charpy tests, will confirm this.

It was long thought that the speed of application of, and the total energy of the blow had an influence upon the energy absorbed in breaking the test-piece. This has now been shown to be a mistaken view. There are several sets of experiments now in existence covering this point, and the author has published the result of investigation,‡ in which it is clearly shown that with Izod impact-pieces breaking with an absorption of 20 ft. lb. to 25 ft. lb. energy, it is immaterial whether the blow be 150 ft. lb. or 50 ft. lb.

Other points have been taken up such as the effect of the temperature at which the test is carried out, and a bibliography is attached to this paper for those interested in the subject, Appendix II.

As regards repeated-impact tests, the total energy required to fracture the test-piece increases as the number of blows required increases. This is largely due to the fact that each blow includes a certain amount of energy necessary to produce the elastic deformation, and this proportion naturally forms the larger percentage of the energy of the blow when the blow is small in value. As to the actual energy absorbed in plastic deformation it is an open question as to how this value is affected with the reduction in the force of the blow. There appears to be in all repeated-impact tests a limiting value of blow which can be indefinitely withstood by the material.
